**Cover image:** The figure on the cover (from Zeyda et al, page 2736) illustrates an experiment using immunofluorescence labeling of cells to assess the effects of teriflunomide, an active metabolite of leflunomide, on the interaction of antigen-induced T cells (green) and antigen-presenting cells (red). The ability of this agent to prevent the formation of conjugates and the immunologic synapse could account for the effects of leflunomide on rheumatoid arthritis and other immune-mediated disorders.
