Background/Purpose: Signaling lymphocytic activation molecule family member 4 (SLAMF4) engagement by its ligand SLAMF2 can mediate the cytotoxicity of CD8+ T cells and natural killer cells. SLE CD8+ T lymphocytes are reportedly defective in cytotoxicity. The aim of this study was to investigate the expression and function of SLAMF4 on SLE CD8+ T cells.

Methods: The expression of SLAMF4 and its adaptor SAP in healthy and SLE T cells were measured by Q-PCR, flow cytometry and western blot. T cells were treated with immobilized anti-SLAMF4 antibodies and the cytotoxic capacity of the T cells was monitored by the cell surface expression of CD107a, reflecting exocytosis of lytic granules.
Results: We found significant downregulation of SLAMF4 and the adaptor molecule SAP gene and protein expression in SLE T cells compared to normal controls. Characterization of the T cell subsets revealed that SLE patients have significantly less SLAMF4 and CD8 T cells compared to normal control T cells, switching the SLAMF4/SLAMF7 ratio in the favor of SLAMF4 and CD8 T cells which have less SAP expression and decreased cytotoxic capacity. SLAMF4 engagement triggers the degranulation of CD8 T cells and SLE T cells have decreased degranulation compared to normal controls. In the effort to explain the loss of SLAMF4 and CD8 T cells in SLE we found that these cells are more likely become double negative T cells and/or die by apoptosis.

Conclusion: Based on our results we conclude that the selective loss of SLAMF4 and CD8 T cells may contribute to the ineffective capacity of fighting against infections in SLE.

Background/Purpose: The interplay between effector and regulatory T cells (Tregs) is a key element among peripheral tolerance mechanisms in Systemic Lupus Erythematosus (SLE). Resistance to suppression has been recently acknowledged as part of the defects shown by T cells from SLE patients. The E3 ligase Cbl-b has been shown to modulate T cell unresponsiveness in SLE. However its potential role in the regulation of peripheral Tregs tolerance has not been fully addressed. The aim of this study was to assess the expression of Cbl-b and its relationship to the resistance to suppression phenotype in SLE patients.

Methods: We included 25 patients with SLE (10 in remission and 15 with active untreated disease) according to the classification criteria of the American College of Rheumatology and 25 age and gender-matched healthy controls. PBMCs were isolated by density gradient and effector (CD4/CD25+) and Tregs (CD4/CD25+/CD127+) were purified by magnetic selection. The expression of Cbl-b and p27kip1 was analyzed by Western blotting. Interaction between Cbl-b and p27kip1 was addressed by immunoprecipitation (IP). Proliferative responses were assessed in allogeneic and autologous cocultures by CFSE. Differences were assessed by t Student test, p < 0.05 was considered as statistically significant. In all cases, an informed consent was obtained, and the ethics committee approved this study.

Results: We found diminished Cbl-b expression in Tregs from SLE patients in comparison to healthy controls (1.3 ± 1.0 vs 2.8 ± 1.8, p = 0.002), which was associated with resistance to suppression in proliferation assays (r = 0.553, p = 0.041). Moreover, this phenomenon was related to deficient expression of the cell cycle regulator p27kip1 in Tregs from SLE patients when compared to healthy controls. We also found by IP assays, that p27kip1 interacts with Cbl-b in Tregs. We found no significant differences regarding to disease activity.

Conclusion: Our data suggest that the ligase Cbl-b is able to regulate the interplay between effector and Tregs, particularly, the resistance to suppression in SLE patients. The E3 Ligase Casitas B Lineage Lymphoma b (Cbl-b) Modulates T Cell Receptor Activation Threshold.

Background/ Purpose: Down-regulation of MAP kinase pathway has been recognized in T cells from patients with SLE that result in hypo-methylation of DNA. RasGRP1 is an intracellular signaling protein highly expressed in T cells and activates the Ras signaling pathway downstream of TCR engagement. RasGRP1 deficient mice develop late-onset lymphoproliferative autoimmune syndrome. Previously we reported that defective (alternatively spliced) RasGRP1 transcripts correlate with lower levels of RasGRP1 protein in SLE T cells. Serin/arginine-rich splicing factor 1 (SRSF1) is a member of the serine arginine family of splicing proteins that binds pre-mRNA to regulate alternative splicing. For instance, SRSF1 binds to the 3’UTR of CD3 zeta and enables normal splicing of this signaling protein. (Moulton V et al J Biol Chem. 2010). The purpose of this study is to determine the relationship between aberrant splicing of RasGRP1 and SRF1 expression in SLE T cells.

Methods: Forty-five SLE patients and eighteen healthy subjects were included in this study. T cells were collected from peripheral blood of each subject and RNA was isolated. Expression levels of SRSF1, normally spliced RasGRP1 and DNM1T1 transcripts were assessed by real time quantitative PCR. Immunoprecipitations (IP) were performed to confirm the direct binding of SRSF1 to RasGRP1 mRNA. SRSF1 specific siRNA was used to suppress the expression levels of the RasGRP1 in Jurkat T cell.

Results: Expression levels of SRSF1 transcripts were significantly lower in SLE patients compared with healthy subjects (p = 0.001, t-test). In patients with SLE, expression levels of SRSF1 correlated with those of normally spliced RasGRP1 and DNM1T1 (r = 0.517, p = 0.023 [RasGRP1]; r = 0.555, p = 0.013 [DNMT1]). IP studies suggested that SRSF1 binds directly to RasGRP1 exon11 RNA. RasGRP1 protein level was decreased in Jurkat T cell when exposed to SRSF1 specific siRNA (Figure).

Conclusion: SRSF1 binds to RasGRP1 mRNA and controls its expression. Low SF2A/5SF levels in SLE T cells correlate with the expression levels of RasGRP1 and DNM1T1. We propose that SRSF1 regulates the alternative splicing of important genes in SLE T cells including RasGRP1 and CD3 zeta.

UC-MSCs Inhibit T Cell Autophagy and Apoptosis in Patients with Systemic Lupus Erythematosus through Mitochondrial Transfer.

Jinyun Chen, Xuebing Feng and Lingyun Sun. The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China.

Background: Systemic Lupus Erythematosus (SLE) is an autoimmune disease that causes inflammation and immune complex deposition in multiple organs. B lymphocytes, CD4+ and CD8+ T cells are involved in the pathogenesis of SLE. We hypothesized that UC-MSCs may inhibit T cell autophagy and apoptosis via activating mitochondrial transfer.

Methods: We assessed autophagy and apoptosis in T cells from SLE patients and healthy controls using the Autophagy Activity Assay Kit and Annexin V/PI detection kit. UC-MSCs and T cells were cocultured in the presence of 5% serum. By the time the T cells were harvested, autophagy and apoptosis levels were measured. The mitochondrial transfer activity of UC-MSCs was assessed by MitoTracker Green FM staining and mitochondrial DNA detection.

Results: Compared to healthy controls, T cells from SLE patients had significantly increased autophagy and apoptosis levels in both autophagy and apoptosis detection kits. UC-MSCs co-cultured with T cells from SLE patients inhibited autophagy and apoptosis levels and reduced mitochondrial transfer activity. UC-MSCs Inhibit T Cell Autophagy and Apoptosis in Patients with Systemic Lupus Erythematosus through Mitochondrial Transfer.
Background/Purpose: This study is aimed to investigate the role of umbilical cord derived mesenchymal stem cells (UC-MSCs) on autophagy and apoptosis in T cells from SLE patients, and to explore the underline mechanisms involved in this process.

Methods: Peripheral blood mononuclear cells (PBMC) were isolated from SLE patients and healthy donors, and cultured under stimulation with anti-CD3/28 antibodies in the presence or absence of autophagy inhibitor 3-MA (5mM for 6h) or activator rapamycin (50nM for 48h). Autophagy levels and apoptotic rates were measured by flow cytometry with the detection of LC3II and Annexin V respectively. To determine the effects of MSCs on T cell autophagy and apoptosis, UC-MSCs were cocultured with T cells at the ratio of 1:10 directly or in transwell system. To observe the changes of pathways upstream of autophagy after MSC treatment, an AMPK activator was added to the cocultures. Meanwhile, mitochondria transmembrane potential (ΔΨm), which was closely related to APPK activation, was marked and measured in MSCs and T cells by MitoTracker Deep Red (MADR).

Results: T cells from SLE patients had both elevated autophagy level and apoptotic rate compared with those from normal controls, which were further increased after anti-CD3/CD28 stimulation. Apoptotic rate of T cells significantly correlated with autophagy level (r=0.570, p<0.0001 for CD4+T; r=0.508, p=0.0011 for CD8+T). Inhibition of autophagy with 3-MA decreased the apoptotic rate of T cells, whereas activation of autophagy with rapamycin increased the apoptotic rate. UC-MSCs significantly inhibited T cell autophagy (22.5±2.4 vs. 36.4±6.3 for CD4+T; 27.2±1.9 vs. 39.2±5.4 for CD8+T, both p<0.05) and T cell apoptosis (22.2±2.6% vs. 49.1±5.7% for CD4+T; 23.3±2.4% vs. 53.2±2.3% for CD8+T, both p<0.05) after cell-to-cell contact coculturing, yet the effect was diminished in transwell system. When AMPK activator added to the cultures, the ability of UC-MSCs to regulated T cell apoptosis was greatly improved. As shown in Figure 1, mitochondria in UC-MSCs could be transferred to SLE T cells when directly cocultured. Consequently, the elevation of ΔΨm in T cells was downregulated after MSC treatment (242.5±8.4 vs. 315.8±5.5, p=0.003 for CD4+T; 139.8±23.5 vs. 199±35.7, p=0.06 for CD8+T), along with the reduction of AMPK.

Conclusion: Autophagy levels are elevated in T cells from SLE patients, leading to aberrant apoptosis. UC-MSCs may inhibit T cell autophagy and apoptosis through mitochondrial transfer.

Figure 1 Transfer of MSC mitochondria to lupus T cells. Mitochondria in MSCs were marked by MitoTracker Deep Red. After cell-to-cell contact coculture, MSC-derived mitochondria were detectable in T cells.

DNA Hydroxymethylation Changes in CD4+ T Cells from Patients with Systemic Lupus Erythematosus. Ming Zhao, Wei Liao, Bochen Zhu, Ruifang Wu and Qianjin Lu. Department of Dermatology, Second Xiangya Hospital, Central South University, Changsha, China.

Background/Purpose: Recent studies have uncovered 5-hydroxymethylcytosine (5hmC) as the sixth base of the genome, and that the Ten-eleven translocation (TET) family proteins is responsible for the generation of 5hmC from 5mC in mammalian cells. 5hmC may function as another epigenetic mark by altering chromatin structure or contributing to the recruitment or exclusion of other DNA-binding proteins that affect transcription. However, the report about DNA hydroxymethylation in CD4+ T cell is SLE is poor, though DNA hypomethylation has been confirmed to contribute to dysregulated mucosal immunity in SLE.

Conclusion: Our study primarily demonstrates that MAIT cells are numerically and functionally deficient in SLE. In addition, we report a novel finding that this MAIT cell deficiency is associated with NK T cell deficiency and elevated PD-1 expression. These abnormalities possibly contribute to dysregulated mucosal immunity in SLE.

DNA Hydroxymethylation Changes in CD4+ T Cells from Patients with Systemic Lupus Erythematosus. Ming Zhao, Wei Liao, Bochen Zhu, Ruifang Wu and Qianjin Lu. Department of Dermatology, Second Xiangya Hospital, Central South University, Changsha, China.

Background/Purpose: Recent studies have uncovered 5-hydroxymethylcytosine (5hmC) as the sixth base of the genome, and that the Ten-eleven translocation (TET) family proteins is responsible for the generation of 5hmC from 5mC in mammalian cells. 5hmC may function as another epigenetic mark by altering chromatin structure or contributing to the recruitment or exclusion of other DNA-binding proteins that affect transcription. However, the report about DNA hydroxymethylation in CD4+ T cell in SLE is poor, though DNA hypomethylation has been confirmed to contribute to dysregulated mucosal immunity in SLE. In this study, we will investigate DNA hydroxymethylation in genome-wide in lupus CD4+ T cells.

Methods: 36 SLE patients and 36 healthy controls were recruited. CD4+ T cells were isolated by magnetic beads. The age and sex were matched. All patients fulfilled at least 4 of the SLE classification criteria of ACR. The content of 5hmC in genome was detected by dot blot: hmDBP-NimbleGen Human 3×720K Promoter Plus CpG Island Arrays was completed for identification of genes with different 5hmC modifications between SLE CD4+ T cells and normal controls. mRNA expression levels were measured by real-time RT-PCR. Gene ontology (GO) was analyzed by the Database for Annotation, Visualization and Integrated Discovery (DAVID). Student's t-test for equality of means was used to compare values. P-values < 0.05 were considered as significant.

Results: Compared with normal controls, the content of 5hmC was increased significantly in lupus CD4+ T cells according to the result of dot blot: hmDBP-NimbleGen Human 3×720K Promoter Plus CpG Island Arrays was completed for identification of genes with different 5hmC modifications between SLE CD4+ T cells and normal controls. mRNA expression levels were measured by real-time RT-PCR. Gene ontology (GO) was analyzed by the Database for Annotation, Visualization and Integrated Discovery (DAVID). Student's t-test for equality of means was used to compare values. P-values < 0.05 were considered as significant.

Activated SLE-T Cells Enhance the Interferon-Alpha Production By Plasmacytoid Dendritic Cells Stimulated By RNA-IC.

**Background/Purpose:** A prominent interferon-α (IFNα) signature is seen in several autoimmune diseases including systemic lupus erythematosus (SLE). Plasmacytoid dendritic cells (pDCs) are the main IFNα producing cells and produce large amounts of IFNα in response to immune complexes containing nucleic acids (ICs). Produced IFNα activates the immune system in a number of ways, including polarization of naïve T helper cells to Th1 cells, expansion and activation of cytotoxic CD8 T cells and enhanced B-cell differentiation and antibody production. Thus, once pDCs are activated they strongly promote the adaptive immune response. However, much less is known about the effects on pDCs by different adaptive immune cells. B-cell differentiation and antibody production. Thus, once pDCs are activated

**Methods:** Human T cells were activated by anti-CD3/CD28 antibodies. T cells or supernatant from T cell cultures were co-cultured with pDCs stimulated by RNA-IC (>20-fold). The frequency of pDCs expressing intracellular IFNα increased when co-cultured with activated CD4+ T cells (5.8%) or CD8+ T cells (6.8%) compared to pDCs cultured alone (0.2%). When cytokines were added to the RNA-IC stimulated pDCs at the same concentration as in the supernatant from activated T cells, both GM-CSF and IL-3 demonstrated a strong stimulatory effect on the IFNα response. The combination of both cytokines increased the IFNα production as much as supernatants from activated T cell. The stimulatory effect of supernatants was significantly reduced after depletion of GM-CSF (92%), blocking of GM-CSF (81%), or its receptor subunits CD131 O.

**Results:** Activated T cells or supernatants from activated T cells increased the IFNα production by pDCs stimulated by RNA-IC -fold. The frequency of pDCs expressing intracellular IFNα increased when co-cultured with activated CD4+ T cells (5.8%) or CD8+ T cells (6.8%) compared to pDCs cultured alone (0.2%). When cytokines were added to the RNA-IC stimulated pDCs at the same concentration as in the supernatant from activated T cells, both GM-CSF and IL-3 demonstrated a strong stimulatory effect on the IFNα response. The combination of both cytokines increased the IFNα production as much as supernatants from activated T cell. The stimulatory effect of supernatants was significantly reduced after depletion of GM-CSF (92%), blocking of GM-CSF (81%), or its receptor subunits CD131 O.

**Conclusion:** Activated T cells enhance the IFNα production by pDCs stimulated by RNA-IC -fold. Association of Adam33 Polymorphisms with Systemic Lupus Erythematosus. Seong-Wook Kang1, Seung-Taek Song2, Su-Jin Yoo, Mi-Kyoung Lim2, Dong-Hyuk Sheen3, In-Seol Yoon2, Jinhyun Kim2 and Seung-Choil Shim3. 1Chungnam National University School of Medicine, Daejeon, South Korea, 2Eulji University Hospital, Daejeon, South Korea.

Background/Purpose: A Disintegrin and Metalloprotease 33 (ADAM33) is a member of a family of genes that encode membrane-anchored proteins with a disintegrin and a metalloprotease domain, and is located on chromosome 20p13. Recently, the polymorphisms in ADAM33 have been found to be associated with asthma. Among the rheumatic diseases, systemic lupus erythematosus (SLE) is a prototypic Th2-mediated autoimmune disease like allergic disorders.

To assess whether genetic functional variants of ADAM33 are associated with susceptibility to SLE or development of specific phenotypes in patients with SLE.

Methods: We have identified 48 SNPs, and nine SNPs were selected with regard to the LD pattern. Genotyping for g.10918G>C, g.12433T>C and g.13506C>G in the ADAM33 gene was conducted with PCR RFLP methods, and genotyping for g.330C>T, g.517A>G, g.8227 G>A, g.9511 G>T, g.12462 C>T, g.12988 C>A polymorphisms was performed by single-base extension (SBE) using the ABI Prism SNPShot Multiplex kit (Applied Biosystems). We conducted an association study for ADAM33 polymorphisms in 190 SLE patients, 469 healthy controls, and 390 rheumatoid arthritis (RA) patients as a disease control. Haplotype analyses of related variants were performed as well.

Results: Significant associations of ADAM33 polymorphisms with susceptibility to SLE were found at g.8227 G>A, g.12988 C>A, and g.13506 C>G (P value were all below 0.001). Polymorphisms at g.8227 G>A was associated with the A NA titers among SLE patients (P = 0.012). In addition, we analysed the haplotype, and found a positive association of susceptibility to SLE with the major haplotype CGCG (P = 3.5E-11). There was no association between ADAM33 polymorphisms and RA as expected.

Conclusion: ADAM33 polymorphisms were strongly associated with susceptibility to SLE and the development of specific clinical manifestations.

Gene Array Analysis Reveals Unique Estrogen Signature in Peripheral Blood Mononuclear Cells of Patients with Systemic Lupus Erythematosus

Stephanie Amici1, Nicholas A. Young1, Lai-Chu Wu2, Mireia Guerau2 and Wael N. Jarjour2. 1The Ohio State University, Columbus, OH, 2The Ohio State University Wexner Medical Center, Columbus, OH.

Background/Purpose: Systemic Lupus Erythematosus (SLE) is an autoimmune disorder predominantly affecting females in the reproductive age range. Estrogen is present at higher levels in this population compared to pre-pubertal and postmenopausal women and has been shown to influence immune cell function by regulating the expression of multiple genes through activation of estrogen receptors (ER) α and β. Recent work using a chromatin immunoprecipitation with ERα has shown that this list may be much larger than what has been characterized to date. In this study, the effects of E2 were examined by comparing gene array expression in peripheral blood mononuclear cells (PBMCs) from premenopausal women with SLE and in healthy premenopausal individuals.

Methods: SLE patients meeting the revised criteria of the American College of Rheumatology, and healthy volunteers were recruited through approved IRB protocols. Whole blood was collected into heparinized tubes and PBMCs were isolated. Cells were cultured with or without 10 nM of 17b-estradiol (E2) for 48 hours. PBMCs were then collected and purified as total RNA and submitted for gene array analysis using HG-U133 Affymetrix® Human Gene Chips. Untreated PBMC arrays served as the internal baseline control for each individual sample and was subtracted from the E2-treated expression values; thus, only the estrogen mediated effect was reported. Data was analyzed using the Multiplot function within the GenePattern software program and with Ingenuity Pathway Analysis Software.

Results: While over 1000 genes were significantly up-regulated over 2-fold in SLE samples when treated with E2, only 236 were identified in corresponding healthy controls. Furthermore, E2 stimulation significantly down-regulated 2530 genes in PBMCs from SLE patients, but only 244 in healthy samples under the same conditions. In concordance, 525 and 1629 genes were found to be uniquely up or down-regulated with E2 treatment in SLE, respectively. Significant E2-mediated regulation of several methyltransferases, including PCMT1 and 9GMDT3, was identified in this analysis. Using Ingenuity Pathway Aanalysis Software, our results identified these genes to be associated with several pathways, including post-translational modification.

Conclusion: These results establish a clear estrogen effect over many genes to produce an estrogen signature, including several genes known to be associated with post-translational modification, and further reveals enhanced regulation in SLE patients when compared to healthy controls.

Nuclear Antibody Positive African-Americans Reveals Distinct Differences in Systemic Lupus Erythematosus and Healthy Anti-Nuclear Antibody Positive African-Americans Reveals Distinct Differences in T Cell and Progenitor Populations

**Background/Purpose:** Systemic lupus erythematosus (SLE) is a systemic autoimmune disorder which arises from both genetic and environmental factors that likely affect phenotypic and functional characteristics of multiple cell lineages. Further, almost all SLE individuals are anti-nuclear antibody positive (ANA+) although ANA positivity does not obligate autoimmune disease. The differences in cellular physiology between ANA+ healthy individuals and individuals that go on to develop SLE remain a critical goal in the understanding of SLE development. A comprehensive view of immune cell phenotypes in disease is often challenging to ascertain due to limits of cell isolation techniques. A comprehensive view of immune cell phenotypes in disease is often challenging to ascertain due to limits of cell isolation techniques. A comprehensive view of immune cell phenotypes in disease is often challenging to ascertain due to limits of cell isolation techniques. A comprehensive view of immune cell phenotypes in disease is often challenging to ascertain due to limits of cell isolation techniques. A comprehensive view of immune cell phenotypes in disease is often challenging to ascertain due to limits of cell isolation techniques.

**Methods:** Blood specimens and information on disease activity were collected from eight African American SLE patients. Patients were matched by age (<5 years), race, and gender to healthy individuals positive for ANA without classifiable lupus (ANA+, n=8) and ANA negative healthy controls (ANA-, n=8). Single-cell analysis of cell surface markers was completed by mass cytometry and cellular heterogeneity was analyzed using SPADE.

**Results:** Compared to both ANA+ and ANA- healthy controls, SLE patients had lower frequencies of cytotoxic CD8+ T cells, regulatory CD4+ T cells and early progenitor cell populations (P<0.05). Significant differences in progenitor cells nodes were found in CD4 and CD8 negative CD3+ T cells and surface marker null progenitor cells. Concentrations of serum sCD40 ligand were significantly lower in patients with SLE compared with ANA+ and ANA- healthy controls (P<0.05). Interestingly, sCD40L production positively correlated with a decrease in regulatory CD4+ T cell populations (P<0.01). Further, IL-7 levels were lower in both ANA+ controls and SLE patients compared with ANA- healthy individuals (P<0.05).

**Conclusion:** Our results indicate that early differences in progenitor cell populations may contribute to decreased levels of regulatory CD8+ and CD4+ T cells and autoantibody production systemically. Furthermore, the decreased production of IL-7, which is important for the differentiation of hematopoietic stem cells into lymphoid progenitors, in SLE patients and ANA+ patients may contribute to early immune defects in progenitor lymphoid populations leading to loss of tolerance in autoimmunity.

The CUL4RBB E3 Ubiquitin Ligase Modulator CC-220 Induces Degradation of the Transcription Factors Ikaros and Aiolos: Immunomodulation in Healthy Volunteers and Relevance to Systemic Lupus Erythematosus

**Background/Purpose:** Systemic lupus erythematosus (SLE) is an immunomodulatory compound that binds to cereblin (CRBN), part of the CUL4RBB E3 ubiquitin ligase complex, which has been shown to ubiquitinate the transcription factors Ikaros (IKZF1) and Aiolos (IKZF3). Polymorphisms at the IKZF1 and IKZF3 loci have been associated with risk of systemic lupus erythematosus (SLE). We explored CRBN, IKZF1, and IKZF3 gene expression in peripheral blood mononuclear cells (PBMC) from SLE patients, the effect of CC-220 on Ikaros and Aiolos protein levels and SLE autoantibody production in vitro, and the impact of CC-220 on immunological parameters in a phase 1, double-blinded, placebo-controlled, single ascending dose, healthy volunteer study.

**Methods:** CRBN, IKZF1, and IKZF3 gene expression was measured by qRT-PCR. Ikaros and Aiolos protein levels were measured by western blot and flow cytometry. Anti-dsDNA and anti-phospholipid autoantibodies were measured from SLE PBMC cultures treated for 7 days with CC-220. In the phase 1 healthy volunteer study, 56 subjects were randomized and enrolled in 7 cohorts, with 6 subjects per cohort receiving a single oral dose of CC-220 (0.03 to 6 mg) and 2 subjects per cohort receiving placebo. CD19+ B cells, CD3+ T cells, and intracellular Aiolos were measured by flow cytometry. IL-7 and IL-1β production were stimulated with anti-CD3 or lipopolysaccharide, respectively, in the TruCulture ex vivo whole blood assay system.

**Results:** Compared to normal PBMC, SLE PBMC expressed significantly higher levels of CRBN (1.5-fold), IKZF1 (2.1-fold), and IKZF3 (4.1-fold). CC-220 treatment of whole blood significantly reduced Ikaros and Aiolos protein levels in B cells, T cells, and monocytes, but not in granulocytes. In cultures of SLE PBMC, CC-220 inhibited anti-dsDNA and anti-phospholipid autoantibody production with an IC50 of ~10 nM. Following administration of single doses of CC-220 to healthy volunteers, there was a treatment-related decrease in intracellular Aiolos, with minimum mean percent of baseline values of ~12% to 28% in B cells and ~0% to 33% in T cells for 0.3 to 6 mg. There was also a treatment-related decrease in absolute CD19+ B cells and CD3+ T cells, with minimum mean percent of baseline values of ~41% to 67% for B cells and ~66% to 73% for T cells for 2 to 6 mg. CC-220 administration also resulted in increased IL-2 (maximum mean percent of baseline values ranging from 247% to 1.896% for 0.1 to 6 mg), and a decrease in IL-1β (minimum mean percent of baseline values of ~11% to 6 mg).

**Conclusion:** These results demonstrate that CRBN, IKZF1, and IKZF3 mRNA are overexpressed in PBMC from SLE patients. Targeting the CUL4RBB E3 ubiquitin ligase with CC-220 resulted in a potent reduction in Ikaros and Aiolos protein levels in B cells, T cells, and monocytes, and inhibited autoantibody production. A diminution of single doses of CC-220 (0.3 to 6 mg) reduced intracellular Aiolos protein expression in B cells and T cells, reduced absolute B cell and T cell counts in the peripheral blood.
increased T cell-derived IL-2 production, and decreased LPS-induced IL-10 production in whole blood ex vivo. These findings support the further development of CC-220 for the treatment of SLE and other autoimmune diseases.

2690

Background/Purpose: Pre-naive B cells represent an intermediate stage in human B cell development with some functions of mature cells, but their involvement in immune responses is unknown. The aim of this study was to determine the functional role of normal pre-naive B cells and possible abnormalities in systemic lupus erythematosus (SLE) that might contribute to disease pathogenesis.

Methods: Pre-naive, naive and memory B cells from healthy individuals and SLE patients were stimulated through CD40 and were analyzed for IL-10 production and co-stimulatory molecule expression, and their regulation of T cell activation. Autoreactivity of antibodies produced by pre-naive B cells was tested by measuring IgM autoantibodies in culture supernatants after different differentiation media. Results: CD40-stimulated pre-naive B cells produce large amounts of IL-10, but did not suppress CD4+ T cell cytokine production. Activated pre-naive B cells demonstrated IL-10 mediated indirect promotion of CD4+ T cell activation, and IL-10 independent impairment of co-stimulatory molecule expression and TNF-α and IL-6 production. IgM antibodies produced by differentiated pre-naive B cells were reactive to ssDNA. SLE pre-naive B cells were defective in producing IL-10, and co-stimulatory molecule expression was enhanced, resulting in promotion of robust CD4+ T cell activation.

Conclusion: There is an inherent and IL-10 mediated mechanism that limits the capacity of normal pre-naive B cells from participating in cellular immune response, but these cells can differentiate into autoantibody secreting plasma cells. In SLE, defects in IL-10 secretion permit pre-naive B cells to promote CD4+ T cell activation, and may, thereby, enhance the development of autoimmunity.

2691

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by overproduction of autoantibodies by B cells and breaking self-tolerance of T cells and dendritic cells (DCs). However, little is known about the relationship between these immune cells in the etiology of SLE. Here, we found a novel DC subset and investigated the interaction among immune cell subsets in SLE.

Methods: Peripheral blood mononuclear cells were obtained from 44 patients with SLE, 20 with rheumatoid arthritis (RA), and 8 healthy controls (HD). Circulating B cells, T cells and DCs were defined based on comprehensive flow cytometric analysis for human immune system termed "the Human Immune Project" by NIH/FHOCIS.

Results: The proportion of central memory B cells, effector B cells, and plasmablasts was higher (p<0.04), while that of IgM memory B cells was lower (p<0.001) in SLE, compared to HD and RA. For T cell subsets, the proportion of effector memory T cells was highest in SLE (p=0.04). For DC subsets which were defined as CD3+CD14+CD19+CD20HLA-DR+, the percentage of CD11c+ myeloid DCs significantly decreased in SLE (p<0.001), while that of CD123+ plasmacytoid DCs was comparable among SLE, HD and RA (p=0.48). Interestingly, DCs that expressed neither CD11c nor CD123 were detected exclusively in SLE but not in the control or RA (p<0.001). To assess pathological relevance of this double-negative DC subset in SLE, we calculated the Pearson product-moment correlation coefficient among immune cell subsets and also conducted correlation clustering analysis. Among them, double-negative DCs characterized with the central memory B cells and plasmablasts, and was correlated with plasmablasts (p<0.04) and negatively with myeloid DCs (p<0.001) and plasmacytoid DCs (p=0.04). Furthermore, the percentage of double-negative DCs was correlated with scores of Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) and the British Isles Lupus Assessment Group (BILAG) index in patients. In 13 patients with treatment-naïve in this cohort, the percentage of double-negative DCs was correlated positively with scores of SLEDAI and BILAG index as well as serum anti-dsDNA antibody levels and negatively with CH50 levels.

Conclusion: These results suggest that a novel CD123+ CD11c+ DC subset characteristically increased in relation to central memory B cells and plasmablasts in patients with treatment-naïve SLE. Furthermore, the frequencies of novel DC subsets were correlated with scores of SLEDAI and BILAG and serum levels of anti-dsDNA antibody, indicating that this DC subset may contribute to disease activity and autoantibody production. A thorough further studies are required, our findings would shed light on the activation mechanism of autoantibody production through the interaction between a novel DC subset and central memory B cells/plasmablasts in SLE and could be potentially useful in the design of new therapeutic strategies.

those with inactive disease (52.9 vs 27.6 %, p = 0.004). Finally, infiltration of CXCR4-expressing CD19+ B cells into the renal interstitium was more prominent in lupus nephritis than IgA nephropathy (p = 0.003).

Conclusion: In SLE patients with active disease, B cells with upregulated expression of CXCR4 and enhanced chemotactic responsiveness towards CCL12 were increased in circulation. These aberrant B cells may be involved in the pathogenic process of SLE by infiltrating into the inflamed organs such as kidneys.

2693
Hyporesponsiveness to TLR9 in Term of Cytokines Production By B Cells in SLE-Patients.

Results: SLE patients had a lower frequency of proliferating B cells upon TLR9 stimulation than HD (p<0.05). B cells from HD significantly upregulated CD38, resulting in a 3-fold increase after TLR9 stimulation, while B cells from HD significantly upregulated any of the surface markers following BLyS stimulation indicating that SLE patients exhibited significantly higher levels of IL-6 in their serum. Furthermore the SLE patients exhibited significantly higher levels of IL-6 in their serum.

Background/Purpose: The role of B cells in immunity has been mainly related to the generation of antibodies and formation of immune complexes. However, B cells can exert additional functions, such as antigen presentation, activation of T cells, formation of lymphoid organs and secretion of cytokines which has not been comprehensively explored in human autoimmunity. In systemic lupus erythematosus (SLE), which is a prototypic autoimmune disease characterized by a breakdown of tolerance toward nuclear antigens, cytokine production induced by toll-like receptor (TLR) 9 is of great interest. It remains unclear to what extent B cells from SLE patients are able to produce cytokine in reaction to TLR9 stimulation.

Methods: Peripheral B cells from 18 SLE patients and 13 healthy donors (HD) were purified from peripheral blood mononuclear cells (PBMCs) by Magnetic Activated Cell Sorting and were stimulated with CpG 2006 in vitro for 48 hours. Subsequently, cell culture supernatants were tested for 28 cytokines (Bio-Plex). In a subgroup of subjects (6 SLE, 10 HD), activation status (CD38 expression), proliferation (% Ki67 positivity), cytokine production and correlated with disease activity, anti-dsDNA titers upon TLR9 stimulation was compared regarding proliferation, activation and cytokine production in reaction to TLR9 stimulation.

Conclusions: B cells from SLE patients and HD upon TLR9 stimulation was compared regarding proliferation, activation and cytokine production and correlated with disease activity, anti-dsDNA titers and CD38 expression following BLyS stimulation indicating that SLE patients exhibited significantly higher levels of IL-6 in their serum.

With respect to monocyte activation SLE patients expressed significantly more CD80, CD86 and HLA-DR in the resting state compared to healthy controls. This baseline hyperactivated state of the SLE monocytes results in up-regulated levels of pro-inflammatory cytokines and increased production of cytokines. The role of B cells in immunity has been mainly related to the generation of antibodies and formation of immune complexes. However, B cells can exert additional functions, such as antigen presentation, activation of T cells, formation of lymphoid organs and secretion of cytokines which has not been comprehensively explored in human autoimmunity. In systemic lupus erythematosus (SLE), which is a prototypic autoimmune disease characterized by a breakdown of tolerance toward nuclear antigens, cytokine production induced by toll-like receptor (TLR) 9 is of great interest. It remains unclear to what extent B cells from SLE patients are able to produce cytokine in reaction to TLR9 stimulation.
Background/Purpose: Systemic lupus erythematosus (SLE) and granulomatosis with polyangiitis (GPA) are autoimmune diseases which develop secondary to immune self-tolerance failure. Both diseases are characterised in part by the production of pathogenic autoantibodies. Although they are different clinically, genetically and immunologically, SLE and GPA may be treated successfully with rituximab, an anti-CD20 monoclonal antibody B cell depleting drug.

The repopulation of B cells post-rituximab is of interest as the timing may differ in different autoimmune diseases and may be associated with serum factors, such as B cell activating factor (BAFF), which promotes B cell survival or with characteristics of specific B cell subsets.

Methods: A prospective longitudinal study of 12 patients with SLE and 12 patients with GPA pre-rituximab and at set intervals post-rituximab with matched autoimmune controls was conducted. Demographic, clinical and laboratory data was obtained in all patients with comparison to healthy controls.

Flow cytometry analysis of transitional B cell, naïve mature B cell and memory B cell subsets was conducted in experiments staining isolated peripheral blood mononuclear cells with antibodies to CD19, IgD, CD27, CD24 and CD38. The expression of α4β7 integrin by B cell subsets was analysed. Plasma BAFF levels were measured by ELISA at baseline, 3 months and 6 months post-rituximab. Statistical analysis was done using GraphPad Prism version 5.

Results: B cells were found to repopulate the blood earlier after rituximab in some cases of SLE compared to GPA. There was no statistically significant difference between the pre-rituximab CD19+ B cell percentage of total lymphocytes in SLE and GPA (p<0.37), however at 3 months and 6 months post-rituximab SLE patients had a greater population of CD19+ B cells in the peripheral blood compared to GPA patients (p=0.02, p=0.001, respectively). Early repopulation was found to be independent of serum factors, but was related to the expression of α4β7 integrin by subsets of B cells. α4β7 integrin expression by T1 and T2 transitional B cells, naïve mature B cells and memory B cells was significantly lower in SLE patients compared to GPA patients pre-rituximab (p<0.0001, p=0.0003, p=0.0008 and p=0.0005, respectively). A separate analysis revealed significantly lower α4β7 integrin expression in the early repopulation group, defined as B cell count > 5 cells/μl 3 months post-rituximab, compared to SLE patients who repopulated the peripheral B cell pool later (p=0.004, p=0.004 and p=0.003, p=0.07, respectively).

Plasma BAFF levels were elevated in SLE and GPA patients pre-rituximab compared to HC (p=0.008, p=0.001 respectively) with a rise in BAFF levels detected in SLE 3 months post-rituximab (p=0.006) but no difference in SLE 6 months post-rituximab (p=0.25). Plasma BAFF levels did not change significantly in the GPA cohort post-rituximab. Plasma BAFF levels were positively correlated with percentage transitional B cells (r=0.44, p=0.04).

Conclusion: There may be an association between the early repopulation of the peripheral blood B cell pool, α4β7 integrin by subsets of B cells and rise in BAFF levels in a cohort of SLE patients.

Relationship Between Soluble sCD23 and B Cell Activation Factor in Patients with Systemic Lupus Erythematosus before and after Rituximab.

Laura Heretiu1, Maria J. Leandro2, Venkat Reddy3, David A. Isenberg1 and Geraldine Cambridge2. 1'Sf. Maria' Clinical Hospital, Bucharest, Romania, 2Centre for Rheumatology, Department of Medicine, University College London, London, United Kingdom, 3Centre for Rheumatology and Musculoskeletal Medicine, University College London, London, United Kingdom.

Background/Purpose: CD23 is the low-affinity receptor for IgE (FceRII). The soluble form, sCD23 is released into the circulation and in vitro this is consistent with clearance from naïve B cells and expression of CD27 (a marker of memory B cells). BAFF (B cell activation factor) is a survival factor for predominantly naïve B cells and is involved in B cell proliferation, plasma cell differentiation and, with APRIL, also class switching. High levels of sCD23 and of BAFF can be present in sera from patients with Systemic Lupus Erythematosus (SLE) and other autoimmune diseases. The interaction between sCD23 and BAFF has not been studied in relation to Rituximab (RTX) treatment.

Aim To investigate the relationship between sCD23 and serum BAFF at baseline and after RTX in patients with SLE.

Methods: Twenty-eight patients with SLE (diagnosed according to the 1982 ACR revised criteria) were studied before B cell depletion therapy (BCDT) based on RTX and 18 SLE patients after RTX treatment. Twenty-eight healthy controls (HC) were also included. Serum sCD23 (normal range given by manufacturers; 1235–5024pg/ml) and BAFF levels were determined using ELISA. Results were analysed in relation with C3 level, anti-ds-DNA titre, IgA, IgG, IgM level and CD19+ B cell count.

Results: Before RTX, sCD23 levels were positively correlated with serum BAFF (p=0.05, r^2 0.47). There was no correlation between sCD23 levels with C3, anti-ds-DNA titre, IgA, IgG or IgM. In HC, sCD23 levels did not correlate with serum BAFF (r^2 =0.23; p=0.10). Further, in patients with levels of sCD23 above the normal range (>5024pg/ml; n=7) median BAFF levels were significantly higher than those with sCD23 within normal limits (n=21) (median BAFF levels: 3.37 and 1.35 ng/ml respectively).

In the 15/28 SLE patients with active disease (BILAG score), there was an even stronger correlation between sCD23 levels and serum BAFF (r^2=0.56, p=0.0001) but no correlation between sCD23 and anti-ds-DNA, IgA, IgG or IgM levels. There was a tendency towards lower C3 values in patients with sCD23 above the normal range. Median BAFF levels were significantly higher in this group (n=6; 5.75 ng/ml) compared to patients with sCD23 within the normal range (n=9; median BAFF: 1.25 ng/ml) (p=0.001).

After RTX, in 10 patients from whom serial samples were available, sCD23 decreased by a median of 39% at 3 months and 56% at 3-6 months consistent with removal of the majority of circulating B cells but levels did not fall below the normal range.

Conclusion: In vitro, the addition of BAFF to B cell cultures stimulated through either Toll-like receptors and the B-cell receptor significantly increased sCD23 cleavage from the B cell surface. Before RTX, serum BAFF levels were related to levels of sCD23 above the normal range in patients with SLE, most markedly in patients with active disease. Serum BAFF is raised in some SLE patients due to changes in availability of BAFF, R-B cell lymphopoenia, BAFF production, or induction by interferons. Germinal center structure is also disturbed in SLE, possibly related to high BAFF levels, which may result in decreased stringency for naïve B cell differentiation into memory phenotype, accompanied by release of sCD23. Levels of sCD23 may be a useful measure of B cell maturation in vivo.

Survival in Systemic Sclerosis-Pulmonary Arterial Hypertension By Serum Autoantibody Status.

Background/Purpose: Previous studies have shown that anticientromere (AC) and isolated nucleolar (NUC) antibodies are the most common autoantibodies in patients with systemic sclerosis (SSc) and World Health Organization (WHO) group 1 pulmonary arterial hypertension (PAH). The goal of the present study was to determine the association between serum autoantibodies and survival in patients with newly diagnosed PAH who are enrolled in the PHAROS (Pulmonary Hypertension and Recognition of Outcomes in Scleroderma) Registry.

Methods: We evaluated patients from the multi-center, prospective, observational PHAROS registry who had definite PAH diagnosed by right-heart catheterization (RHC) (mean pulmonary artery pressure (mPAP) ≥ 25mmHg and pulmonary capillary wedge pressure (PCWP) ≥ 15mmHg) within 6 months of enrollment. Medical history, laboratory (including serum autoantibodies), pulmonary function test, echocardiogram, 6-minute walk distance, and RHC data were collected at baseline and biannually or as clinically indicated. Mortality data were collected from participating centers' medical records and/or the Social Security Death Index. Kaplan-Meier estimates for survival were determined for 6 different autoantibody groups. Multivariable Cox regression analyses were performed to assess risk of death by hazard ratios (HR) in each autoantibody group, controlling for age, sex, SSc disease duration (defined as duration since first Raynaud symptom), forced vital capacity (FVC) % predicted, and skin score.

Results: 163 PHAROS subjects met WHO group 1 PAH criteria and had serum autoantibody information available (7 missing autoantibody data, 7 with negative autoantibodies). More than half had either AC or NUC; 61 (36%) subjects had AC, 39 (23%) NUC, 11 (6%) AC and Scl70, 28 (16%) had mixed/other, 9 (5%) RNA polymerase III (RNApol), 8 (5%) U1RNP autoantibodies. The mean SSc disease duration at PAH diagnosis was longest for AC (19.3±13.4y) and shorter for NUC patients (12.2±9.8, compared to AC p=0.02). Thirty-two (21%) subjects died over the mean follow-up time of 2.4±1.7 (median 2.0, range 0-7.2) years. 1- and 3-year survival across all antibody groups was 93% and 77%; 1- and 3-year survival estimates were 94% and 72% for AC; 94% and 79% for NUC; 89% and 63% for Scl70; 100% and 88% for RNApol; 92% and 79% for mixed/other. No patient with RNApol or negative autoantibodies died over the follow-up period. For all autoantibody groups, unadjusted and adjusted HR

2698

Optimizing Scleroderma Centers of Excellence: Perspectives from Patients and Scleroderma (SSc) Experts.

Background/Purpose: SSc is a complex, diffuse, devastating health condition of vascular injury, inflammation and fibrosis resulting in multiple organ-system derangements with high impact on survival and quality of life. Demonstrated research activity tends to define SSc Centers of Excellence (SCoEs) certification. However, SSc complications require coordinated high-level multi-specialty expert care. The Scleroderma Foundation in partnership with the Scleroderma Australia and Scleroderma Society UK engaged SSc patients and SSc health providers (HPs) in a multi-tiered process to assess priorities in recognition of SCoEs.

Methods: A mixed methods design ensured comprehensive item collection in addressing 'important qualities and services in a certified SSc Center of Excellence'. A core of 35 patients, SSc HPs from 8 countries initiated the process through an iterative process using nominal group technique with rounds of item collection modification and review until saturation and satisfaction of proposed survey content was achieved and subsequently field-tested with a 5 point scale (critical to low importance). Participation was screened and "gate-controlled" with online survey access through a unique one-time link. Telephone interview was offered for accessibility. Responses from SSc patients showed statistically significant association between risk of death and autoantibody positivity.

Conclusion: Anticientromere and NUC autoantibodies are prevalent in SSc patients with PAH. PAH may be a late complication in AC patients, but may occur earlier in SSc patients with other autoantibodies. There does not appear to be a significant association between SSc antibody type and survival in patients with PAH.

patients and HPs were compared by Pearson’s X² or Fisher’s exact tests as appropriate.

**Results:** Initial phases yielded a 54 item survey that was field-tested in 15 SSc patients and HPs. 400 patients and SSc HPs received surveys of which 299 from 19 countries (75% response rate) were completers. Expert care superseded research as a priority of ‘critical importance’ by HPs and patients respectively at 69% and 48% (p = 0.02) and by 94% and 89% (p = 0.8) when ‘critical to very important’ were collapsed. 3 questions provided internal cross-validation of this query. “SCoEs should engage in research” received 57% of patients and 48% of HPs (p = 0.02) as being critical. Further, education, rehabilitative services and support networks were consistently highly rated items with topics stratified by ratings (Tables 1 & 2). Discrepant areas of importance between patients and HPs are highlighted in tables.

**Conclusion:** Participation was robust in all project stages emphasizing the perceived global importance of this effort. Though research is of clear importance, quality expert care incorporating rehabilitative and educational provisions is a SCoE operational priority. These findings signal the need to redefine SCoE certification standards and provide a roadmap to SCoE development.

**Background/Purpose:** Anti-SSc polymerase III antibodies (anti-SSc III) are one of the most frequent antinuclear antibodies identified in systemic sclerosis (SSc), with an estimated prevalence of 11% (95% CI: 8–14) (1). Anti-SSc III has been associated with some clinical characteristics linked with a poor prognosis such as diffuse cutaneous involvement or renal crisis. More recently, anti-SSc III have been suggested to play a role in immunological response to cancer (2). This study aimed to (i) confirm this clinical phenotype in a new French cohort followed by a systematic review and meta-analysis of the literature; (ii) test whether unknown clinical associations could be highlighted by a meta-analysis.

**Methods:** One hundred and thirty tree consecutive and unselected SSc patients were tested for anti-SSc III. Clinical characteristics were retrieved from our database. PubMed and EMBase were searched for all references providing clinical characteristics of anti-SSc III positive and negative (controls) SSc patients. Meta-analysis was performed using number of anti-SSc III positive and controls patients, clinical characteristics and organ involvement.

**Results:** Twelve patients were found to be anti-SSc III positive in our cohort. Anti-SSc III was associated with diffuse cutaneous involvement (p = 0.02), myositis, renal crisis and cancer (p = 0.01). The systematic review retrieved 112 abstracts from 2003 references, which were read in full-text. Forty-five studies were finally included in the meta-analysis. The number of studies providing data for each clinical association was comprised between 4 and 26; between 256 to 1098 anti-SSc III positive patients and 2088 to 6612 controls were included in analysis. Anti-SSc III were positively associated with diffuse cutaneous involvement, joint involvement, renal crisis, heart involvement and cancer; and negatively associated with female sex. There was no association between anti-SSc III and esophageal involvement, pulmonary hypertension, interstitial lung disease, digital ulceration, and myositis (Table 1).

**Conclusion:** This meta-analysis confirmed that SSc patients with anti-SSc III are at higher risk of severe skin extension, renal crisis and cancer. Merging results from numerous studies also highlighted less known associations such as joint and heart involvement. Patients carrying anti-SSc III should benefit from an appropriate screening of these potentially severe complications.

Relevance of the 6-Minute Walking Test in Assessing the Severity and Outcome of Pulmonary Arterial Hypertension Associated with Systemic Sclerosis, without Extensive Interstitial Lung Disease.

Background/Purpose: In pulmonary arterial hypertension (PAH) associated with systemic sclerosis (SSc), no study has yet evaluated the correlation between the 6-minute walking test (6MWT) distance and the right-heart hemodynamic parameters, in SSc-PAH patients without extensive interstitial lung disease (ILD). As the ILD correlation between the baseline 6MWT total distance and the RHC hemodynamic variables remains important in this test, during follow-up, a weak correlation persists between Δ6MWT and ΔmPAP, but not with ΔCI. These results question the relevance of the 6MWT as an outcome measure for SSc-PAH patients.

Methods: Patients with definite SSc (according to ACR 1987 and/or Leroy criteria), RHC-proven pre-capillary PAH and no extensive ILD on chest HRCT were enrolled. The Δ6MWT (total distance was non-significantly and weakly correlated with ΔmPAP (r = 0.20, p = 0.15) and with ΔPVR (r = 0.17, p = 0.22). Similar results were found on the validation cohort, but reached statistical significance (ΔmPAP : r = 0.20, p = 0.03 ; ΔPVR : r = 0.29, p = 0.008). There were no correlation between Δ6MWT total distance and ΔCI in both cohorts.

Conclusion: To our knowledge, this study is the first to prove a correlation between the baseline 6MWT total distance and the RHC hemodynamic parameters, in SSc-PAH patients without extensive ILD. As the CI explains only 8–21% of the distance, the weight of confounding comorbidities remains important in this test. During follow-up, a weak correlation persists between Δ6MWT and ΔmPAP, but not with ΔCI. These results question the relevance of the 6MWT as an outcome measure for SSc-PAH patients.

Key Roles for Mir-155 and Mir-21 in Progressive Lung Fibrosis Associated with Systemic Sclerosis (SSc-ILD).

Background/Purpose: We have already reported that macrophage activation, and up-regulation of TGF-beta and interferon-regulated genes are involved in progressive SSc-ILD. Micro-RNAs (miRNA) are a class of small noncoding RNAs that control gene expression and are eventually involved in most biological processes. Therefore, we analyzed simultaneously miRNA and mRNA in the same prospective cohort of SSc-ILD patients in order to explore their complex network and the miRNA’s involvement in progressive lung disease.

Methods: Lung tissue was obtained by open lung biopsy in 22 consecutive SSc-ILD patients (11 diffuse and 10 limited cutaneous SSc patients; 5 controls). High-resolution computerized tomography (HRCT) was performed on baseline and 2–3 years after treatment that was based on lung histologic classification. Microarray analysis (mRNA and miRNA) was performed and the results correlated (Pearson’s) with changes in HRTC score (FibMx). MirConnX software was used to explore the gene regulatory network between mRNA and miRNA. The study was approved by the Institutional Review Boards from both universities (Brazil and USA).

Results: As already shown, despite treatment, most of SSc-ILD patients progressed based on delta FibMx (p < 0.01). Lung mRNA microarray analysis distinguished SSc-ILD from controls (FDR-corrected, q < 0.25) with 185 miRNA genes (present in 25%) that had significant differential expression. The miRNA microarray analysis also confirmed the altered expression of hundreds of genes in our SSc-ILD cohort and MirConnX simultaneous analysis of miRNA and mRNA showed 4 relevant miRNAs in the center of this multifaceted regulation (graphical): mir-182, mir-141, mir-155, and mir-195 (graphical). Pearson’s correlation between miRNAs and the top-50 most upregulated miRNAs in SSc-ILD compared to controls showed that mir-155 was strongly correlated (r = 0.5) with 32/top-50 genes, such as IL12A and DHFR. mir-21 was the second most correlated (22/top-50 genes), followed by mir-195 (21/top-50 genes), mir-141 (22/top-50 genes), and mir-182 (19/top-50 genes). mir-155 and mir-21 were also strongly negatively correlated with several top-downregulated mRNA genes, including IL12A, with r = 0.70. A heatmap of the most informative miRNAs showed mir-155 clustering together with mir-21, a known mRNA involved in idiopathic lung fibrosis; and both mir-155/mir-21 expression were strongly correlated (r = 0.6). Surprisingly, only 4 miRNAs were correlated to the delta FibMx: mir-155 (r = 0.65), mir-182 (r = 0.49), mir-27a (r = 0.49), and mir-21 (r = 0.47).

Conclusion: Mir-155 and mir-21 were the center of this complex altered gene expression in the lungs of SSc-ILD. Moreover, these miRNAs were key for the progression of the lung fibrosis based on a CT score. Together, anti-miRNA therapy might be a novel target to prevent progressive SSc-ILD.
Elevated Serum Levels of Endostatin in Mixed Connective Tissue Disease - Association with Pulmonary Fibrosis and Digital Ulcers. Siilje Reiseter1, Ragnar Gunnarsson2, Torhild Garen3, May Britt Lund1, T. Mogens Aalokken4, Anna M. Hoffmann-Vold1, Øyvind Molberg1 and Thor Ueland5. 1 Institute of Clinical Medicine, University of Oslo, Oslo, Norway. 2 Department of Rheumatology, Oslo University Hospital Rikshospitalet, Oslo, Norway. 3 Department of Respiratory Medicine, Oslo University Hospital Rikshospitalet, Oslo, Norway. 4 Department of Radiology, Oslo University Hospital Rikshospitalet, Oslo, Norway. 5 Research Institute for Internal Medicine, University of Oslo, Oslo, Norway.

Background/Purpose: Mixed Connective Tissue Disease (MCTD) is a chronic, immune-mediated disorder defined by the combined presence of serum anti-RNP antibodies and selected clinical features of Systemic Sclerosis (SSc), Systemic Lupus Erythematosus and Polymyositis. Previous studies have revealed increased values of endostatin and Vascular Endothelial Growth Factor (VEGF) in MCTD (1) and SSc (2), suggesting that an altered angiogenic balance might play a pathogenic role in both diseases. The aim of this study was to evaluate the serum levels of endostatin and VEGF in MCTD, compared to SSc and Healthy Controls (HC).

Methods: Sera of MCTD patients (N=169) from the cross-sectional nationwide Norwegian MCTD cohort (n=136) and the Norwegian Systemic Tissue Disease and Vasculitides Registry (NOSVAR) (n=33) were assessed. 170 SSc patients (N=310) were included from NOSVAR. Age- and sex-matched healthy blood donors were included as HC (N=100). Clinical parameters examined in MCTD patients were: digital ulcers (N=136), pulmonary fibrosis (N=158) and Forced Vital Capacity (FVC) % of predicted value (N=142). Pulmonary fibrosis was defined according to the Fleischner Society classification system for high-resolution CT Abnormalities. Serum levels of endostatin and VEGF were assessed by ELISA and compared by Means (M) and Standard Deviation (SD) in all groups. Statistical differences were analyzed by the independent sample t-test with significance level P < 0.05.

Results: The levels of endostatin were higher in the MCTD group (M:SD) 83.0(24) ng/ml compared to HC 65.1(12) ng/ml (P < 0.001), but lower compared to SSc 93.0(37) ng/ml (P < 0.001). The levels of VEGF in MCTD were not different compared to HC and SSc. However, levels of VEGF were elevated in SSc vs. HC (251.8(185) vs. 186.1(130) ng/ml, P < 0.001). MCTD patients with digital ulcers had higher endostatin levels than MCTD patients without digital ulcers (79.6(21) ng/ml, P < 0.05). Mean endostatin levels were increased in MCTD patients with pulmonary fibrosis 90.5(33) ng/ml compared to MCTD without pulmonary fibrosis 79.9(20) ng/ml (P < 0.05). Correspondingly, MCTD patients with VFC < 80% had higher endostatin levels 94.5(33) ng/ml than MCTD patients with VFC ≥ 80% 81.8(21) ng/ml (P < 0.05).

Conclusion: MCTD patients have significantly elevated serum levels of endostatin, but not elevated serum levels of VEGF. Increased circulating levels of endostatin can indicate dysregulation of angiogenesis in MCTD, particularly in patient subgroups with digital ulcers and pulmonary fibrosis.

Fatigue in Systemic Sclerosis. Didem Uzunaslan1, Caner Saygin2, Tufan Torun2, Mehmet Ozdemir2 and Gulen Hatemi2. 1 University of Istanbul, Cerrahpasa Medical Faculty, Rheumatology, Istanbul, Turkey. 2 Istanbul University, Cerrahpasa Medical Faculty, Rheumatology, Istanbul, Turkey.

Background/Purpose: Fatigue is a frequently reported disabling symptom for patients with systemic sclerosis (SSc). It has a major impact on overall quality of life including work, family and social life. Our aim is to evaluate the frequency of fatigue among SSc patients compared to healthy and diseased controls and to delineate the factors associated with fatigue.

Methods: We included SSc and rheumatoid arthritis (RA) patients who visited our outpatient clinic for their routine follow-up and healthy controls recruited from hospital staff. Comprehensive physical examination with nailfold capillaroscopy and assessment of Rodnan skin score (RSS) were performed by a single physician. Health assessment questionnaire disability index (HAQ-DI), multidimensional assessment of fatigue (MAF) scale, fatigue impact scale (FIS), Beck depression inventory (BDI) were filled by all participants. Having a score of ≥ 5 in FSS was tabulated as having fatigue for statistical analysis. Multivariate regression analysis was performed to determine the factors associated with high fatigue scores in SSc.

Results: Seventy patients with SSc, 52 RA patients and 100 healthy controls were included in this study. MAF scores were significantly higher among RA patients (p < 0.0001), followed by SSc patients (p < 0.013) compared to healthy controls. Similarly, HAQ scores in SSc were higher than healthy controls. The frequency of fatigue, determined by FSS score, was significantly higher with 77% among RA patients (40 out of 52 scored ≥ 4 on the FSS) (χ² = 47.58, df = 2, p = 0.0001), followed by SSc patients of whom 60% (42 out of 70) reported high FSS scores (χ² = 9.402, df = 1, p = 0.002). SSc patients who experienced fatigue had higher frequency of skin pigmentation (72.9% vs. 45.5%, p = 0.002), GI involvement (70% vs 35%, p = 0.007), and higher HAQ (1.26 vs 0.54) and BDI scores (24.7 vs 12, p < 0.001). The components of HAQ-DI which were significantly higher among SSc patients with fatigue were VAS-Raynaud (1.53 vs 0.32), VAS-digital ulcer (1.36 vs 0.32), VAS-GI (1.2 vs 0.39), and VAS-general (1.87 vs 0.76). In multivariate analysis, RSS (p = 0.016, β = 0.365, 95%CI = 0.28–0.45), pulmonary arterial hypertension (p = 0.043, β = 0.258, 95%CI = 0.009–0.504), VAS-digital ulcer (p = 0.036, β = 0.339, 95%CI = 0.009–0.271), and VAS-GI (p = 0.016, β = 0.169, 95%CI = 0.032–0.297) were independent predictors of fatigue.

Conclusion: A round two-thirds of our SSc patients reported higher levels of fatigue. This increase in fatigue correlated with the extent of skin sclerosis, pulmonary hypertension and patient-reported digital ulcer and gastrointestinal involvement severity.

Background/Purpose: Systemic sclerosis (SSc) is a systemic disease characterized by cutaneous and visceral fibrosis, presence of autoantibodies and vasculopathy. The central nervous system has, however, been rarely studied. Therefore the aim of this study is to determine cerebral and corpus callosum abnormalities in SSc and to determine the possible relationship between atrophy and SSc related features.

Methods: A total of 41 SSc patients (37 female; mean age = 50.8; SD = 13.2) and sixty-six health age and sex matched volunteers (37 female; mean age = 51.4; SD = 12.3) were included. A complete clinical, laboratory and neurological evaluation was performed in all subjects. Cognitive evaluation was performed using the Montreal Cognitive Assessment (MoCA). Individual scores 26 were considered impaired. Mood disorders were determined through Beck’s Depression and Beck’s Anxiety Inventories. SSc patients were further assessed for clinical and laboratory SSc manifestations, disease activity (Valentini Activity Index), severity activity (Medsger Severity Index). Total dose of corticosteroids and other immunosuppressant medications used since the onset of the disease were calculated. MRI scans were performed in a 3T Phillips® scanner. Sagittal T1 weighted were used for cerebral volume and corpus callosum volume in both dSSc (r = -0.05; p = 0.02) and lSSc (r = -0.06; p = 0.14) or corpus callosum volume (r = -0.06; p = 0.14).

Conclusion: dSSc have significant smaller cerebral and corpus callosum volumes when compared to lSSc and healthy controls. Structural abnormalities are observed in SSc patients with cognitive impairment and mood disorders. Disease activity and organ damage showed no correlation with cerebral volume and corpus callosum volume in this population.

Ulnar and Radial Stenosis in Systemic Sclerosis. María Eugenia Lara1, Mariano Rivero1, Julia Romero1, Guadalupe Palacios1, Ignacio Carrillo2, Claudia L. Giraldo3, Amalia Schiell4, Hugo Armando Laborde4, Marina Khoury4, Saez Diego4, Gustavo Citera5, Oscar L. Rillo5 and Juan C. Barreira6. 1British Hospital, Buenos Aires, Argentina, 2Instituto de Rehabilitación Psicofísica, Buenos Aires, Argentina, 3Hospital Gral. de Agudos Dr. E. Tomú, Buenos Aires, Argentina, 4Hospital General de Agudos Dr. E. Tomú, Buenos Aires, Argentina.

Background/Purpose: Systemic sclerosis (SSc) is a chronic, autoimmune disease. Endothelial damage has been recognized as the initial pathogenic factor. The involvement of the microvasculature is well defined, whereas the prevalence of large vessels disease is still unknown. We aim to describe the frequency of ulnar and radial stenosis in SSc patients and analyze the correlation between arterial stenosis and digital ulcers.

Methods: We included 57 SSc consecutive patients who fulfilled ACR 1980 classification criteria and 21 healthy controls. SSc patients were classified in two groups: those with present or past digital ulcers and those without them. We collected demographic, clinical and laboratory information. The control group was constituted with volunteers who attended spontaneously to our hospital to make an image study. All participants have done an arterial ecodoppler of both arms, looking for ulnar and radial stenosis. Statistical analysis: Mann-Whitney, Fisher test p<0.05, Odds Ratio (OR), Forward Stepwise Hosmer and Lemeshow test.

Results: The prevalence of stenosis in at least one arterial was observed in 18 of 57 patients with SSc (31%) and in none of the 21 controls (p=0.003). Stenosis occurred in at least one radial artery in 9 of 57 SSc patients (15%) and in one of 21 controls (p=0.19). Univariate analysis is shown in Table 1. In the multivariate model, the best predictors of digital ulcers were age at onset of Raynaud phenomenon before 40 years (OR 5.3 95%CI 1.54–18.22, p=0.008) and presence of late SD pattern (OR 4.4 95%CI 1.29–15.63, p=0.018). The area under ROC = 0.76 and the Hosmer and Lemeshow test was not significant (p=0.54). Ulcers probability calculated by the model and observed in the sample by combining groups with different predictors is presented in Table 2.

Conclusion: In the present series, ulnar stenosis was observed frequently in SSc patients. However, the size of the sample did not allow adjusting for potential confounders. Stenosis of large vessels in SSc patients was not associated with presence or history of digital ulcers. The best predictors of digital ulcers were age at onset of Raynaud phenomenon before 40 years and the presence of late SD pattern.

Systemic Sclerosis Related Calcinosi...
Background/Purpose: Calcinosis is a disabling, rarely discussed manifestation of SSc for which the natural history and management is poorly understood. Last year, the Scleroderma Clinical Trials Consortium (SCTC) established a task force to develop a calcinosis specific patient reported measure (PROM). This investigation is the 1st phase of a multi-tiered project.

Methods: Four focus groups and individual interviews in the US and UK were recorded and transcribed verbatim. To capture both pathophysiologic and life impact, 2 questions were asked: 1. Since developing calcinosis how has your life changed over time? 2. How has the calcinosis changed over time? Patients were also asked to frame questions to help a physician learn if calcinosis was better, worse or the same. Transcripts underwent an iterative inductive process (no preconceived coding, content drives coding and analysis) by at least 5 independent analysts including at least one research team member with SSc. Concepts were triangulated to identify a comprehensive set of meaningful concepts with occurrence quantified per participant.

Results: Twenty-three patients (22/23 female, 19/23 white, with mean disease duration 14.8 years) were consented and interviewed. Responses broadly included concepts of self-management strategies and recurrent hypotheses relating calcinosis development to trauma, Raynaud’s and cold exposure. We identified discrete concepts which are described in Table 1 along with the proportion of patients declaring personal relevance.

Cold exposure and Raynaud’s were a perceived association to calcinosis severity - “when they are cold mine always open back up”. Several described a disabling core body phenomenon involving decreased core temperature with sensation of freezing, feeling of being cold, “like ice”, and all described a feeling of intense rigidity - “it’s like intense - it racks your whole body”. Calcinosis tended to present along with or soon after SSc diagnosis and remained throughout disease duration.

A majority of patients engage in strategies to extrude calcinosis with either pressure +/- soaking or at home surgical techniques. “I actually have homemade surgical tools to get these out.” The following anchors were consistently indicated to assess calcinosis severity: pain level, size, frequency, number and functional impairment.

Conclusion: Patient observations and self-management behavior provide opportunities to learn from and to preemptively educate physicians and patients. Patients are eager for self-management guidance. These concepts provide the groundwork for PROM development. However, as suggested by patients, a composite of scales anchored in pain, size, frequency, number and related impairment may reasonably serve as an interim instrument for SSc calcinosis until that time.

Table 1. Concepts from patient focus groups and interviews. The participants not represented by either affirmations or denials did not discuss the designated issue.

Calcinos Physical Properties

| Rock-like/soft calcinosis | 52% | “... hard as a rock” |
| Paste-like                | 22% | “It was quite like toothpaste” |
| Fluid/Leaking             | 44% | “I’ve always had peeling and leaking” |

Extrudes with warm soaking 23% –
Calcinos recurrent, once appears in any site 30% –

Effects/Sensations of Calcinos

- Pain
  - Constant 43% –
  - Tender 91% –
  - Throbbing 91% –
  - Like skin has been burned (hot, coals, flame etc) 26% –
  - Sharp - ‘like glass shards’ 22% –
  - Tight with pressure 57% – “feels like something is trying to get out” –

- Feel calcinos growing 48% –
- Relief with extrusion of calcinos 70% –
- Itchy 9% –
- Development of Ulcer secondary to calcinos 52% –
- Infection related to calcinos 70% –

Functional Effects of Calcinos

- Interferes with ADL’s 87% – “I can’t even hold her” (referring to baby)
- Interferes with work 91% –
- Interferes with walking 22% –

Perceived Influencing Factors

- More frequent in cold or not practicing cold prevention 35% – “I know winter’s coming because these come up... Become tight”
- More frequent when Raynaud’s worse 43% –
- Trauma or banging interferes with healing 43% –
- Response to warmth or prevention against cold 35% – “I haven’t taken the kind of care I’m used to with my gloves on... now it’s the first time again with this”
- Response to cyclophosphamide 13% – “not since I was treated with Cytoxan... they totally stopped coming”
- Response to vasodilating medications 9% –
- Response to colchicines 4% – “she gave me colchicine, it was doing exactly what she said softening the calcinos”

Self-Management

- Self-Manages with topical antibiotics 30% –
- Self-Manages with cushioning (if malatial doesn’t hurt) 70% –
- Self-Manages by extrusion with pressure +/- warm soak 35% – “contact with viater helps them to drain”
- Self-Manages by extrusion with instruments at home 22% – “I just got a large darning needle and pushed it in”
- Need Self-Management Protocols for Calcinos 87% –

Patient-suggested anchors to assessment questions

- Pain 91% –
- Interferes with work / daily activities 74% –
- Size 61% –
- Number 43% –
- Ask about wounds 1st then proceed to ask about calcinos 13% –
- Location 9% –

Tuesday, November 18
Background/Purpose: Vascular involvement is a key feature of Systemic sclerosis (SSc) and involves both the micro and macrovasculature. Vascular changes are central in the disease’s pathogenesis and the assessment of vascular involvement has a prognostic value; therefore vascular assessment has a pivotal significance, both for research and clinical purpose.

A non invasive technique to monitor cutaneous vascular function is the response to a physiological challenge using laser speckle contrast imaging. This technique has proven effective and reproducible for the assessment of skin blood flow in SSc patients, either with or without dynamic challenge.

The aim of our study was to evaluate post-occlusive reactive hyperemia test (PORH) in consecutive SSc patients and to test whether PORH is a useful tool to discriminate different disease subsets within SSc population.

Methods:

Patients

Starting from to april 2011 to june 2014, 54 consecutive SSc patients were enrolled (mean age 56 ±15 years, F/M =18). Patients were divided into limited SSc (n=29), Diffuse SSc (n=8) and Very early SSc (VEDOSS) (n=17) according to literature definition.

Laser Speckle Contrast Analysis

Cutaneous blood flow was measured throughout the experiments using a high frame rate LSKI (Pericam PSI system, Perimed, Jarfalla). The occlusive ischemic test was performed by inflating for 4 minutes a cuff placed on the left arm to 30 mm Hg above the systolic pressure. The recovery time (time needed to recover the basal flux after occlusion in seconds), the peak flux (hyperemic peak reached after occlusion) and the area under the hyperemic curve were recorded.

Statistical analysis

Correlation between clinical data and laser measurements were performed by non parametric tests and contingency tables for cathegorical variables (StatView, SAJ). In view of the high number of comparisons involved, only p values equal or below 0.01 were considered significant.

Results: A statistical significant difference was detected in the post-ischemic hyperemic peak flow between very early SSc and established SSc (424 vs 137% p = 0.0001). PORH peak flow decreased according to capillaroscopic pattern (early=435%, active=173%, Late=145% P<0.005). Moreover a strong correlation between capillary density and peak flow was unveiled (rho=0.56, p < 0.0001).

Conclusion: These data show a different pattern of vascular involvement in early SSc as compared to established disease that mirror capillaroscopic changes. In this context, functional features of early and established disease seem to be the physiologic counterpart of abnormalities detected by capillaroscopy. PORH test might be a useful aid for further characterization of vascular involvement in SSc.

Joint and Tendon Involvement Predict Severe Disease Progression in Systemic Sclerosis: A Prospective Study.

Joining synovitis (HR, 1.26, 95% CI 1.00–1.58) and TFRs (HR: 1.67, 95% CI 1.01–2.75) were independently predictive of overall disease progression, as were also the diffuse cutaneous subset (HR: 1.30, 95% CI 1.05–1.61) and positive antitopoisomerase-I antibodies (HR: 1.25, 95% CI 1.02–1.53).

The mean change of mRSS over the follow-up period was 9.4±4.11, and 99/123 patients (80%) had a progression of at least 5 points. Joint synovitis (HR: 1.63, 95% CI 1.05–2.55) and TFRs (HR: 1.67, 95% CI 1.01–2.75) were independently predictive of overall disease progression.

Conclusion: This first report of the prospective follow-up of EUSTAR patients identified for the first time the merit of baseline synovitis and extended previous data for tendon friction rubs in early SSc patients. These results obtained through the largest worldwide database support the use of these easily detected clinical findings for the risk stratification of SSc patients. These parameters might be used in the future to select high-risk patients, guide therapies and might be regarded as potential surrogate markers for severity.

Nailfold Videocapillaroscopy in Healthy Children and Adolescents: Description of Patterns of Normality.

Daniela Piotto, Julianna Sekiyama, Cristiane Kayser, Mariana Yamada, Claudia A. Len and Maria Teresa Terreri.

Joint synovitis was predictive of the occurrence of new digital ulcer(s) (HR: 1.45, 95% CI 1.08–1.96) and decreased left ventricular ejection fraction (HR: 2.20, 95% CI 1.06–4.57); TFRs were confirmed to be an independent predictor of scleroderma renal crisis (HR: 2.33, 95% CI 1.03–6.19).

Conclusion: This first report of the prospective follow-up of EUSTAR patients identified for the first time the merit of baseline synovitis and extended previous data for tendon friction rubs in early SSc patients. These results obtained through the largest worldwide database support the use of these easily detected clinical findings for the risk stratification of SSc patients. These parameters might be used in the future to select high-risk patients, guide therapies and might be regarded as potential surrogate markers for severity.

Background/Purpose: Video capillaroscopy (VCP) allows for the evaluation of capillary dimensions and to quantify the degree of microangiopathic alterations in autoimmune diseases. However, studies in healthy subjects and specially in children and adolescents are limited. To describe the normal pattern of capillaries by VCP in healthy children and adolescents, and to evaluate the inter and intraobserver concordance in capillary measurements.

Methods: Cross-sectional study of 100 healthy participants aged 5 to 18 years by VCP. The capillary dimensions (capillary loop length, capillary width, inter capillary distance) and the number of capillaries/mm were evaluated under 100x magnification, acquiring three consecutive images of nine capillaries per individual, totaling 900 capillaries examined and photographed. Four age groups were studied: 5-7 years (17 individuals); 8-10 years (24 individuals); 11-14 years (30 individuals) and 15-18 years (29 individuals). The intra and inter observer concordance was tested in 25% of subjects by two professionals with experience in this method.

Results: The capillary dimensions (mean ± SD) were: capillary loop length 278.6 ± 60.3 μm, inter capillary distance 124.1 ± 28.1 μm, capillary width 15.0 ± 2.6 μm and 7.8 ± 1.5 number of capillaries/mm. The only significant difference between males and females was the inter capillary distance which was higher in girls (p = 0.011). When comparing the four age groups, only the intercapillary distance remained constant over time (p = 0.088). Teenagers between 15 and 18 years had longer and thicker capillaries (318.7 ± 50.4 μm) and (16.2 ± 3.3 μm) resp. when compared to other age groups (p < 0.001 and p = 0.012 respectively). We also found an increase in the number of capillaries/mm with age: 6.1 capillaries/mm (5–7 years); 7.0 (8 to 10 years); 8.0 (11–14 years) and 9.3 (15–18 years) (p < 0.001). There was a good intra and interobserver concordance in the analysis of capillary dimensions and the number of capillaries/mm by VCP. In VCP, 11% had enlarged capillary (capillary width percentile> 97.5) and 10% avascular areas (inter capillary distance percentile> 97.5). There was a negative correlation between the distance and the number of capillaries/mm.

Conclusion: This study evaluated the normal pattern of VCP in healthy children and adolescents and stratified patients by age groups. The number of capillaries/mm, the length and thickness of the capillary increased with age, while the intercapillary distance was maintained over the years.

Background/Purpose: The American College of Rheumatology (ACR) and the European League Against Rheumatism (EULAR) suggested the 2013 ACR/EULAR classification criteria for systemic sclerosis (SSc), due to the lack of sensitivity for early and limited SSc of the 1980 ACR classification criteria.

The aim of this study was to determine how many patients with Raynaud phenomenon are reclassified as SSc by the 2013 ACR/EULAR classification criteria for SSc and to analyze the predictive variables of the new classification criteria in those patients.

Methods: We applied the 2013 ACR/EULAR classification criteria for SSc to 60 patients who had been diagnosed as SSc according to the 1980 ACR classification criteria (SSc group) and 64 patients who presented Raynaud phenomenon with or without autoimmune disease, but did not fulfill the 1980 ACR classification criteria (Raynaud phenomenon group). We analyzed the discrepancy between the previous and the new classification criteria when subjects were categorized as those with SSc.

Results: All patients who were diagnosed as SSc according to the previous classification criteria fulfilled the new criteria. Furthermore, 17 of 64 patients (26.5%) in Raynaud phenomenon group were reclassified as SSc by the new criteria. Reclassified SSc patients in Raynaud phenomenon group significantly showed less frequency of scleroderma, sclerodactyly, finger pitting scar, interstitial lung disease and higher frequency of telangiectasia than those in SSc group (Table 1). Eleven of 17 patients who were reclassified as SSc (64.7%) had anti-centromere antibody. But none of 17 patients had anti-topoisomerase 1, meanwhile 29 of 60 patients who had been diagnosed as SSc (43.8%) had anti-topoisomerase 1 (Table 1). On multivariate linear regression analysis using variables with significance, puffy finger, sclerodactyly and telangiectasia were significant predictive values for the new classification as SSc in Raynaud phenomenon (RR = 23.7, 29.5, 14.2; p values <0.001, 0.015, 0.031).

Conclusion: 26.5% patients, who presented Raynaud phenomenon but did not fulfill the 1980 ACR classification criteria for SSc, were reclassified as SSc according to the 2013 ACR/EULAR classification criteria. Also, we suggest that physicians should pay attention to puffy finger, sclerodactyly and telangiectasia in patients with Raynaud phenomenon for the early diagnosis of SSc.

Table 1. Comparison of characteristics, clinical manifestations and autoantibodies between reclassified systemic sclerosis patients in Raynaud phenomenon group (New SSc) and patients in systemic sclerosis group (SSc).

Background/Purpose: The Duruöz Hand Index (DHI) is a reliable tool for the evaluation of hand’s function in patients with scleroderma. The aim of our study was to adapt and to validate the DHI questionnaire in an Argentinian population with scleroderma.

Methods: For validation, 3 rheumatologists adapted and translated to Spanish the original version in French and the final version was re-translated to French by a bilingual person. To evaluate the construct validity, we used the patient global visual analogue scale (VAS), VAS for questions for the same activity, the health assessment questionnaire (HAQ) and the Rodnan. A subsample attended a second visit to evaluate reproducibility, with no modifications in the treatment in relation to the previous visit. Continuous variables were expressed as mean and standard deviation (SD) or medians with their interquartile range (IQR). Spearman’s correlation coefficient was used to quantify the degree of correlation between the different VAS, HAQ and Rodnan with the total score. The intraclass correlation coefficient (ICC) was used to assess reproducibility and Cronbach’s alfa to evaluate internal consistency.

Results: 45 patients diagnosed with scleroderma were included in the study. 84.44% were women, mean age of 51 ± 13.72 years (SD). 48.89% were Mestizos, while 46.67% were Caucasians with a disease duration of 24 months (IQR: 18–60). 64.44% patients had diagnostic of limited scleroderma: 77.78% were right handed and 53.33% had extra cutaneous manifestations. Raynaud was present in 93.33%, pitting scars in 33.33% and digital ulcers in 26.67%. The median score of the total questionnaire was 4.5 (IQR: 0–26) of the global VAS 49 (IQR: 10–50), of HAQ 0.3 (IQR: 0–1) and of Rodnan 5 (IQR: 2–11). The correlation between the total score of DHI and the patient global VAS was 0.58, with the HAQ was 0.63 and with Rodnan 0.08. The correlation coefficient between the VAS and each group of questions for the same activity in the DHI questionnaire, indicated good correlation for the questions that refer to activities of dressing (0.69; 0.65; 0.57), for hygiene (0.61; 0.56), and for the office questions (0.56; 0.73). There was excellent level of correlation with those related to fine motor activities with a maximum r value of 0.78. The reproducibility was 0.88 (CI 95% 0.76–0.99) and the internal consistency according to Cronbach’s alfa was 0.98.

Conclusion: The results from this study show the DHI to be a reliable and valid test for this Argentinian population with scleroderma.

Development of a “Renal Crisis Prevention Card” As an Educational Tool Aimed at Improving Outcomes in High-Risk Patients with Systemic Sclerosis. Lee S. Shapiro,2,4,5 Lesley Ann Saketko,2,4,5 Jessica F. Farrell,2,4 and Kim Filigelstone3. 1The Center for Rheumatology, Albany, NY; 2Louisiana State University Health Sciences Center, New Orleans, LA; 3Royal Free Hospital, Scleroderma Unit and Scleroderma Society, London, United Kingdom.

Background/Purpose: Scleroderma renal crisis (SRC) is a devastating complication of SSC. The introduction of effective treatment with ACE inhibition (ACE-I) in 1979 dramatically reduced death as a near-immediate consequence of SRC. However, poor outcomes still occur with great frequency including chronic or temporary dialysis or death. Individuals with early, rapidly progressive diffuse disease and RNA polymerase III antibody positivity are at high risk for SRC. Prophylactic use of ACE-I in high risk patients has not demonstrated improved outcomes and may have negative consequences. Our goals were to identify associative causes of poor outcome and develop a targeted preventive intervention to address in accordance with findings.

Methods: A retrospective chart review at Royal Free Hospital scleroderma clinic between 1994–1999 identified and stratified 44 cases of SRC for long term outcomes (death, long-term dialysis, short-term dialysis, and no dialysis). Cases were then assessed for factors potentially related to outcomes: onset of symptoms, time to medical attention, and therapeutic management. Results directed development of SRC preventive intervention.

Results: Death or long-term dialysis was the outcome in approximately 50% of the cases reviewed. Three subgroups emerged as associated with poor outcomes:

1. SSc patients with no previously established SSc diagnosis presenting as “malignant hypertension”
2. SSc patients with an established SSc diagnosis but uninformated about SRC and misinterpreted symptoms or failed to recognize the urgency of seeking medical attention
3. SSc patients who presented promptly for urgent outpatient medical care informing physician of SSc diagnosis, but were incorrectly treated with therapies other than ACE-I or initiation of ACE-I was without sufficiently rapid dose adjustment to achieve blood pressure control.

Poor outcomes were correlated to delayed therapy, rather than drug failure. All patients in the ‘no dialysis/death’ group were treated with ACE-I according to protocol. From these findings, a “scleroderma renal crisis prevention card” was developed. See image.

Conclusion: Despite availability of effective therapy, SRC is associated with poor outcomes often consequential to treatment delay and lack of knowledge of initial treating physicians. A “renal crisis prevention card” may improve health outcomes of high-risk patients as a method of educating patients and health care providers.

Comparison of PROMIS® survey Between Scleroderma Patients in an Academic Center and Patient-Based Scleroderma Foundations. Vivek Nagaraja1, Veronica Berrocal1, Keri Connolly1, Ann Kennedy2, Daniela Seelmann2 and Dinesh Khamán2. 1University of Michigan, Ann Arbor, MI, 2Scleroderma Foundation, Boston, MA, 3Federation of European Scleroderma Associations, Tournai, Belgium, 4Universidad de Los Andes, Santiago, Chile.

Background/Purpose: The National Institutes of Health Patient-Reported Outcomes Measurement Information System (PROMIS®) roadmap initiative is a cooperative research program designed to develop, evaluate, and standardize item banks to measure patient-reported outcomes (PROs) across different medical conditions as well as the US population (www.nihpromis.org). It has comprehensive item banks that assess physical, mental, and social well-being. The aim of this study was to compare the PROMIS survey between the scleroderma patients at an academic center and patient-based foundations as this has implications for large epidemiological studies (such as Scleroderma Patient Intervention Network).

Methods: A study titled ‘PROMIS in rheumatology’ was created in the Assessment center website. This study contained 13-PROMIS instruments. Patients seeking care in the academic Scleroderma clinic were approached to participate in the PROMIS survey. Patients were also recruited from the Scleroderma patient-based foundations (SF) namely – the Scleroderma Foundation and the Federation of European Scleroderma Associations through the respective social media pages and e-newsletters. Averager T-scores of the patient-based foundation scleroderma cohort were compared with those of the UM scleroderma patient cohort.

Results: Thirty-six patients at UM and 241 patients from SF have so far completed the survey. In both groups, the T-scores in the following domains were approximately 1 standard deviation worse than the United States (US) general population (GP) – fatigue, physical function, pain interference, satisfaction in roles and activities. Anger and social isolation banks were comparable to US GP. In comparison to the UM scleroderma cohort, the T-scores of the SF patient cohort was significantly worse for pain behavior and social isolation (Table, p < 0.05); however, the differences were not clinically meaningful.

Conclusion: The patients with SSc have decrements in health-related quality of life on PROMIS measures when compared to the US general population. There were no meaningful differences in the two cohorts, suggesting that patients from scleroderma clinic and patient foundations can be approached for non-pharmacologic intervention trials.

The UCLA Gastrointestinal Tract Questionnaire (GIT) 2.0 and GI Visual Analogue Scale(GI-VAS) Reflect Different Aspects of GI Involvement in Systemic Sclerosis. Y ossra Suliman1, Yasser Shaweesh2, Suzanne Kafaja3, Lewis Duan4 and D. E. Furst5. 1Fatih Sultan Mehmet State Hospital, Istanbul, Turkey, 2Trakya University Medical Faculty, Edirne, Turkey, 3Medical Faculty, Edirne, Turkey, 4Scleroderma Foundation and the Federation of European Scleroderma Associations, Tournai, Belgium, 5University of California Los Angeles, Los Angeles, CA.

Background/Purpose: UCLA GIT2.0 is a validated measure for assessing the severity of gastrointestinal involvement in systemic sclerosis patients (SSc) patients; GI VAS is also a widely used measure of GI effect in patients as a component of SSc health assessment questionnaire (SHAQ). GIT2.0 includes 34 questions in 7 domains (reflux, distention, soilage, diarrhea, social function, emotional wellbeing and constipation). GI VAS is a 100 mm VAS that asks the patient; how much GI symptoms interfere with patient function. Both are measures of present state.

Objectives
1) Is there a correlation between GI-VAS and total GIT2.0?
2) Is a correlation between GI-VAS and GIT2.0 domains?
3) Does total GIT2.0 or GI-VAS predict patient global.

Methods: We extracted baseline data in 38 consecutive SSc patients, with respect to: age, sex, SSc subtype, disease duration, HAQ-DI, VAS for; pain, raynaud’s ulcer, breathing, GIT2.0 domains and patient global. An analysis: Correlation between GI-VAS and domain and individual domains by Pearson correlation Coefficient. Univariable linear regression using patient global as dependent variable against total GIT2.0 or GI-VAS as separate independent elements. Independent variables were: SSc subtype, age, gender, disease duration, VAS for: raynaud’s, ulcer, fingers and breathing in each model.

Results: Of total 98 patients available for analysis, 84 were females, 59 were diffuse subtype, mean age 54.6 (SD 14), mean disease duration 9.6 years (7.6), total GIT2.0 mean 50.51 (0.49) – moderate, GI-VAS mean 52.34 (2.77)– mild, HAQ-DI mean 0.98 (0.76) and patient global mean 3.77(2.69).

Conclusion: Correlation between GI-VAS and GIT2.0 (total and individual domains) are listed in table. Even though the correlation between GIT2.0 and GIT VAS is (r=0.6) and weighted kappa is 0.59 – moderate, thirty four percent of the patients showed disagreement between the two measures by at least 1 category (total of four categories). Linear regression analysis demonstrated that GIT2.0 and GI-VAS were independent predictors of patient global as well as VAS for breathing and ulcer (p<0.007). A desired r squared for GIT2.0 was 0.49and for GI-VAS was 0.51.

Performance of the New ACR Criteria in Systemic Sclerosis: A Multi-center Study. Necati Cakir1, Omer Nuri Pamuk2 and Mehmet Ali Balci3. 1Fatih Sultan Mehmet State Hospital, Istanbul, Turkey, 2Trakya University Medical Faculty, Edirne, Turkey.

Background/Purpose: Reliable and validated classification criteria are needed to conduct high quality clinical research in systemic sclerosis (SSc). The most widely used classification criteria for SSc are ACR criteria published in 1980. Recently, ACR and EULAR Collaborative Initiative has proposed a new set of criteria for the classification of SSc. In our study, we aimed to compare the sensitivity and specificity of the new ACR/EULAR criteria to the ACR criteria in our SSc population.

Methods: Two rheumatology centers from Turkey participated in this study. The features present at disease onset in patients with SSc seen between 2008-2013 were retrospectively reviewed. For the evaluation of specificity, patients admitted to each center between the same time period for conditions other than SSc, in whom AANA was deemed necessary within the diagnostic work-up, were included as controls.

Results: Onehundradandtwo SSc patients (93 females, 9 males, mean age: 47.9±13.9) and 80 controls (70 females, 10 males, mean age: 48.4±11.6) were included into the study. AANA was positive in 89.2%,
anti-Scl-70 in 31.7%, and anti-centromere in 21.6% of the patients. Digital ulcers were present in 34.7% of SSc patients, pulmonary hypertension in 42.2%, interstitial lung disease in 36.3%, and renal crisis in 2%.

The sensitivity of ACR/EULAR and ACR1980 criteria were, respectively, 92.2% and 78.4%. The specificity of ACR/EULAR and ACR1980 criteria were, respectively, 89.3% and 76.7%. According to the new criteria more patients were misclassified, and according to ACR1980 criteria 18 patients were classified. The sensitivity of ACR 1980 criteria was significantly better in SSc patients with interstitial lung disease when compared to others (91.7% vs. 74.1%, p=0.036). According to the New criteria set, however, the sensitivity tended to be higher in the group with anti-Scl-70 positivity (91.7% vs. 74.1%, p=0.09). The sensitivity and the specificity of the criteria were not different in patients with certain other clinical features or other antibody positivities.

Conclusion: We observed that the new ACR/EULAR SSc classification criteria had better sensitivity and specificity in our SSc patients; and it led to misclassification in a larger number of patients.

Prevalence and Features of Metabolic Syndrome in Systemic Sclerosis.
Tiago N. Amaral1, Karina Pereira2, Naiul A. Sinicato1, Sandra Gasparini1, Fernando Augusto Peres3, Maria Carolina de Souza1, Ana Paula del Rio4, João Francisco Marques-Neto5 and Simone Appenzeller6. 1State University of Campinas, Campinas, Brazil, 2State University of Campinas, Limeira, Brazil, 3University of Campinas, Campinas, Brazil, 4State University of Campinas, Limeira, Brazil, 5University of Campinas, Campinas, Brazil, 6Faculty of Medical Science, State University of Campinas Unicamp, São Paulo, Brazil.

Background/Purpose: Systemic sclerosis (SSc) is a multisystem autoimmune disease characterized by initial vascular injuries and resulted fibrosis of skin and internal organs. Vascular impairment in SSc involves both micro and macrovascular circulation and maybe a sign of endothelial dysfunction. Metabolic syndrome (MetS) in SSc.

Methods: We screened consecutive SSc patients followed in a longitudinal cohort from 2011 to 2013 and age and sex matched controls. We excluded patients with overlapping rheumatic diseases. Predefined outcome measures were collected. This included demographics (age, gender, disease duration), physical examination [skin score, joint count, blood pressure, height, weight, waist circumference (WC) and hip circumference (HC)], disease activity (Valentini Disease Activity Index) and severity (Medger Disease Severity Scale) scores and laboratory data (total and fractions of cholesterol, fasting glucose levels, basal insulin, C3, C4, erythrocyte sedimentation rate and hemoglobin/hematocrit levels). MetS was assessed using the definition recommended by the 2009 Joint Interim Statement (JIS). Nonparametric tests and correlation were used for statistical analysis.

Results: A total of 131 SSc (121 female; mean age = 51.70; SD=13.12) and 79 health subjects (69 female; mean age=40.66; SD=13.38) were included in the study. Seventy-eight (59.54%) patients had limited SSc (lSSc), 42(32.06%) had diffuse SSc (dSSc) and 11(8.4%) SSc sine scleroderma disease (ssSSc). Active disease was observed in 18(13.74%) SSc (10 lSSc); 42(32.06%) had diffuse SSc (dSSc) and 11(8.4%) SSc sine scleroderma disease (ssSSc). Active disease was observed in 18(13.74%) SSc patients. Hypertension was identified in 35 (26.72%) SSc and 8 dSSc) patients. Hypertension was identified in 35 (26.72%) SSc patients, and in 8 dSSc) patients. Hyperension was identified in 35 (26.72%) SSc patients. Hypertension was identified in 35 (26.72%) SSc patients and 8 dSSc) patients. Hypertension was identified in 35 (26.72%) SSc patients and 8 dSSc) patients. Hypertension was identified in 35 (26.72%) SSc patients and 8 dSSc) patients. Hypertension was identified in 35 (26.72%) SSc patients and 8 dSSc) patients. Hypertension was identified in 35 (26.72%) SSc patients and 8 dSSc) patients. Hypertension was identified in 35 (26.72%) SSc patients and 8 dSSc) patients. Hypertension was identified in 35 (26.72%) SSc patients and 8 dSSc) patients. Hypertension was identified in 35 (26.72%) SSc patients and 8 dSSc) patients. Hypertension was identified in 35 (26.72%) SSc patients and 8 dSSc) patients. Hypertension was identified in 35 (26.72%) SSc patients and 8 dSSc) patients. Hypertension was identified in 35 (26.72%) SSc patients and 8 dSSc) patients. Hypertension was identified in 35 (26.72%) SSc patients and 8 dSSc) patients. Hypertension was identified in 35 (26.72%) SSc patients and 8 dSSc) patients. Hypertension was identified in 35 (26.72%) SSc patients and 8 dSSc) patients. Hypertension was identified in 35 (26.72%) SSc patients and 8 dSSc) patients. Hypertension was identified in 35 (26.72%) SSc patients and 8 dSSc) patients. Hypertension was identified in 35 (26.72%) SSc patients and 8 dSSc) patients. Hypertension was identified in 35 (26.72%) SSc patients and 8 dSSc) patients. Hypertension was identified in 35 (26.72%) SSc patients and 8 dSSc) patients. Hypertension was identified in 35 (26.72%) SSc patients and 8 dSSc) patients. Hypertension was identified in 35 (26.72%) SSc patients and 8 dSSc) patients. Hypertension was identified in 35 (26.72%) SSc patients and 8 dSSc) patients. Hypertension was identified in 35 (26.72%) SSc patients and 8 dSSc) patients.

Conclusion: This is the first study to determine the prevalence and features of MetS in SSc. MetS is frequently observed in SSc and not associated with disease related features in this cohort. However MetS should be routinely screened since it can influence athosclerosis and cardiovascular mortality in SSc.

T cell Biology in Lupus, Vasculitis, Myositis and Other Autoimmunity
Tuesday, November 18, 2014, 8:30 AM – 4:00 PM

2722
Rapamycin Corrects GATA-3 Deficiency in Lupus Treg.
Hiroshi Kato and Andras Perl. SUNY Upstate Medical University, Syracuse, NY.

Background/Purpose: As demonstrated by the negative correlation between Treg frequency or suppressive function and SLE disease activity index score, it is tempting to speculate that a Treg defect contributes to dysregulated immune response in SLE. GATA-3 is not only indispensable for Th2 differentiation, but also plays critical roles in homeostasis and function of Tregs as exemplified when Treg-specific deletion of GATA-3 leads to spontaneous development of inflammatory disorder. GATA-3 deficient Tregs have reduced FoxP3 expression and are poised to express IL-17 in the presence of IL-6. However, roles of GATA-3 in lupus Treg biology remain undefined.

Methods: CD3+ T cells were isolated from 9 pairs of matched SLE and healthy control (HC) subjects. A part of the CD3+ T cells were stained with CD4, CD8, and CD25 followed by GATA-3 and FOXP3. The rest of the cells were cultured in RPMI culture media with 10% FCS, 1% Penicillin/Streptomycin, and 1% L-glutamine for 3 days in the presence of plate-bound anti-CD3 and soluble anti-CD28 with or without 100 nM rapamycin. After 3 days of culture period, cells were stained as previously described. GATA-3 expression by CD4+, CD8+, and CD4+ CD8+ double-negative (DN) T cells as well as CD4+ CD25+ FOXP3+ Treg was assessed by flow cytometry. MFI fluorescence intensity was normalized to that of HC samples on day 0.

Conclusion: The data points to GATA-3 deficiency in SLE Treg as a potential mechanism underlying the functional incompetence. Rapamycin may correct Treg function by restoring GATA-3 expression in SLE.

Disclosure: H. Kato, None; A. Perl, None.

2723
Programmed Death 1 Inhibits T-Cell Adhesion By Regulating Rap1.
Inbar Alagut1, Marianne Straza2 and Adam Mor3. 1NYU, New York, NY; 2NYU Langone Medical Center, New York, NY.

Background/Purpose: Programmed Death-1 (PD-1) is an inhibitory co-receptor that is highly expressed in T lymphocytes. The binding of PD-1 to its ligands, PD-L1 or PD-L2, is vital for the physiologic regulation of the immune system. Likewise, a major function of the PD-1 signaling pathway is the inhibition of self-reactive T cells, which serve to protect against autoimmune disease. PD-1 transmits its inhibitory effects by dephosphorylation of physiologically associated proximal signaling molecules that are downstream of the T cell receptor complex.

At the cellular level, PD-1 activation can lead to depression of T-cell proliferation, impaired survival, and decreased interleukin-2 release.

Methods: Preliminary studies have shown that PD-1 also inhibits T cell adhesion, but little is known how this is mediated. In order to fill this gap, we investigated the role of PD-1 in T-cell adhesion by analyzing the major players in its TCR signaling pathway. We hypothesized that PD-1 inhibited adhesion by inhibiting Rap1, a small GTPase vital for effective T cell motility and adhesion.

Results: We identified that when PD-1 binds to its ligand PD-L2 there is an inhibition of Rap1 activation and LFA-1 mediated adhesion. We continued to show that C3G, a vital component of activating Rap1 and a more upstream element in the TCR signaling cascade, is dephosphorylated by PD-1.

Moreover, this was mediated by the phosphatases SHP-1 and SHP-2. Interestingly, we did not see these results downstream the inhibitory coreceptors, CTLA-4, proving that PD-1 works by a distinct mechanism.

Conclusion: We concluded that PD-1 inhibits Rap1 mediated adhesion by dephosphorylation of C3G utilizing the phosphatases SHP-1 and SHP-2. Further studies are underway to further characterize the regulation of these enzymes by PD-1.

2724
Deficiency of Ro52/TRIM21 in Different Subsets of Peripheral Blood Mononuclear Cells from Patients with Inflammatory Myopathies.
Andreas Galindo-Feria1, Jadranka Gamo-Martin2, Ana Barrera-Vargas3, Javier Merayo-Chalico and Jorge Alcocer-Varela. Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico.

Background/Purpose: The detection of Ro52/TRIM21 autoantibodies has been considered an independent prognostic marker in different rheumatic conditions. However, the information about the expression of Ro52/TRIM21 in subsets of peripheral blood mononuclear cells (PBMCs) in autoimmune diseases is scant. Specifically, its role in idiopathic inflammatory myopathies (IIM) has not been elucidated, and the evaluation of its expression in these diseases is the aim of the present study.

Methods: We included active, untreated patients with recent diagnosis (<1 month) of IIM according to Bohan and Peter’s criteria, who attended a referral center from March 2013 to April 2014. Patients with diagnosis of dermatomyositis (DM), polymyositis (PM) and antisynthetase syndrome (AAS), as well as age and gender-matched healthy controls were recruited. All subjects gave informed consent and the study was approved by the institutional ethics committees. PBMCs were isolated by Ficoll-Hypaque method and different subsets of PBMCs (CD4+, CD8+, CD14+) were purified by magnetic selection. The expression of Ro52/TRIM21 was evaluated by Western Blot. Descriptive statistics are shown with mean and standard deviation. Student’s T test or Mann-Whitney U test was used to analyze differences between groups.

Results: We included 14 patients with IIM (1 PM, 3 AAS, 10 DM), as well as 14 healthy controls. Sixty percent of subjects were female, with a mean age of 43 ± 15 years. CPK levels at diagnosis were 4534 ± 2235 U/L and lymphocyte count was 1021 ± 170 cells/µL. The presence of myositis-specific and associated autoantibodies was assessed by ELISA. The autoantibodies found in DM patients were anti-Ro52 (20%) anti-PL7 (20%), anti-Ku (20%), anti-PL12 (10%), anti-SRP (10%) and anti-Mi2 (10%). In AAS patients, anti-Ro52 (33.3%), anti-Jo1 (33.3%) and anti-PMSc17 (33.3%) were identified. We did not find any specific nor associated autoantibodies in the patient with PM. Patients with IIM showed decreased protein expression of Ro52/TRIM21 in comparison to healthy controls in different PBMC subsets: total PBMC: 0.971 ± 0.603 vs 1.849 ± 0.927, p = 0.016, CD4+ lymphocytes: 0.797 ± 0.540 vs 2.413 ± 0.786 p = 0.007, and monocytes: 0.875 ± 0.358 vs 1.890 ± 0.209 p < 0.001. CD8+ lymphocytes from IIM patients also showed a trend towards lower Ro52/TRIM21 expression (0.902 ± 0.708 vs 0.540, p = 0.133). We did not find significant differences among each of the IIM groups.

Conclusion: Our findings suggest that patients with IIM are characterized by deficient expression of the ubiquitin ligase Ro52/TRIM21 in different PBMC subsets (CD4+ lymphocytes and monocytes). Further insights into the function of this protein will have profound implications for the understanding of IIM. TRIM21 deficiency could be particularly related to decreased IRF ubiquitination and degradation, which could enhance type 1 interferon signaling.

Background: Primary Sjogren’s Syndrome (pSS) is a systemic autoimmunity disease characterized by the presence of anti-Ro/SSA (SS-A) and anti-La/SS-B (SS-B) autoantibodies in >90% of affected individuals. Diffuse disease of salivary glands is a frequent feature of pSS. CCR9, a member of the chemokine receptor family, is expressed on T follicular helper (Tfh) cells and Tfh-like cells and on naïve T cells. A main role of CCR9 is to facilitate the homing of Tfh-like cells to secondary lymphoid tissues. CCL25 is a ligand for CCR9 and plays a central role in Tfh cell development. Upregulation of CCL25 levels in salivary glands of pSS patients may favor the accumulation of Tfh-like cells in the gland and contribute to disease pathogenesis. In this study we aimed to investigate the expression of CCR9 and CCL25 in salivary glands of primary Sjogren’s syndrome patients (pSS).

Methods: A few milligrams of the salivary glands were harvested from 12 patients with pSS and six controls. Frozen sections were used for immunohistochemistry (antibodies against CCR9, CCL25, CD3, CD20, and CD38). CCR9+/CD3+ and CCR9+/CD38+ cells were quantified using ImageJ software. CCR9 and CCL25 expression levels were determined by qRT-PCR and Western Blot.

Results: The expression of CCR9 and CCL25 was significantly higher in pSS patients compared to healthy controls. The percentage of CCR9+ cells was increased in pSS patients (p<0.05). Similarly, the expression of CCL25 was significantly higher in pSS patients (p<0.05).

Conclusion: The expression of CCR9 and CCL25 is significantly increased in salivary glands of pSS patients compared to healthy controls. This finding suggests that CCR9+ and CCL25+ cells may contribute to the pathogenesis of pSS.

Disclosure: None.
Background/Purpose: In primary Sjögren’s syndrome (pSS) B cell activation and autoantibody secretion are hallmark immunopathological features. Specific lymphoid organization (including germinal centers) is associated with increased risk for development of extraglandular manifestations and lymphoma. Thus better understanding of the cellular and molecular pathways that underlie formation of ectopic lymphoid structures is of pivotal importance. Tfh cells, expressing ICOS and cytokines like IL-21 play a critical role in the formation of such structures and in activation of B cells. Recently, a novel subset of CD4+ T cells was found to have Tfh-like characteristics and was found to be specifically attracted to mucosal sites by CCL25, the ligand for CCR9.

Objective: To investigate the presence of CCL25 and CCR9-expressing Tfh-like cells in pSS patients.

Methods: Levels of CCL25 were measured in the serum of patients with pSS (n = 13), non-Sjögren’s sicca (nSS, n = 15) and healthy controls (HC, n = 10) by Luminex was determined. Secretion of CCL25 by labial salivary gland (LSG) biopsy samples from pSS (n = 14) and nSS (n = 14) patients was assessed and CCL25 mRNA was quantified (n = 9 vs n = 9). CCR9-expressing cells were assessed in the circulation of HC and pSS patients and expression of Tfh markers including CXCR5, ICOS and PD-1 was analyzed.

Results: Increased CCL25 levels were observed in serum of pSS and nSS patients as compared to HC (pSS 2984 ± 286, nSS 2692 ± 177, HC 2140 ± 154, p = 0.02 and p = 0.03 resp). CCL25 serum levels in pSS correlated with the presence of chemokines involved in formation of ectopic lymphoid structures CXCL13 and CCL19 (r = 0.594, p = 0.04) and proinflammatory cytokines IL-12 (r = 0.615, p = 0.03) and TWEAK (r = 0.621, p = 0.03). In addition, pSS patients displayed a 10 fold increase in CCL25 mRNA levels in LSG (p < 0.05) and an increase in CCL25 protein levels in LSG washouts compared to nSS patients (2029 ± 2986 vs 974 ± 188 pg/mL, p = 0.03). In contrast, CCL25 protein levels in HC did not increase. The number of CCR9-expressing T cells in the circulation as compared to HC (14.1% vs 7.9%, p < 0.05). Interestingly, to CCL25 a substantial proportion of CCR9+ cells expressed CXCR5, PD-1 and ICOS.

Conclusion: Our results suggest that enhanced expression of CCL25 in the labial salivary gland might promote elevation of CCR9-expressing Tfh-like cells at the site of inflammation. Considering the expression of ICOS and the capacity of CCL25 to induce proinflammatory cytokine secretion it suggests that the CCL25/CXCR5/CCR9 axis might play a role in the immunopathology of pSS, representing a novel therapeutic target in this disease.

T Cells Trigger Intestinal Pneumonia in Polyomaviruses. Akira Takeda1, Y asut suku Fukushima2, Takaji Matsutani3, Y ichiro Hagi3, Chisun M in4, Ryo Rokutanda3, Y asuhiro Suyama5, Mitsu masa Kishimoto6, Ken-ichi Yamaguchi7, and Masao Okada8.

The lung is frequently affected in connective tissue diseases (CTDs). Polyomaviruses (PM) is a major CTD characterized by idiopathic inflammatory lesions of muscle and other organs including critical pulmonary involvement. Intestinal lung diseases, mainly interstitial pneumonia (IP), have been recognized in 30–70% of PM patients, which often have a poor prognosis and a high risk of mortality. While the presence of myositis-specific autoantibodies suggests an autoimmune etiology of PM, the pathogenesis of PM-associated IP remains unclear. The aim of this study was to elucidate the role of T cells in this pulmonary complication. Lung tissue was utilized in this study with the approval of the IRB.

Methods: We had advantage of a rare opportunity to be able to precisely study the lesions caused by PM by using a video-enhanced thoracoscopic surgery after successful video-assisted thoracoscopic surgery from the cases of earliest-stage IP associated with PM: one patient with IP of early usual (IP) pattern and another patient with IP of nonspecific IP (NISP) pattern. It lead us to immunohistochemically characterize the phenotype of lung-infiltrating lymphocytes from the lung biopsy specimens, and to analyze T-cell receptor (TCR) and T-cell receptor (TCR) alpha-chain (TCR V alpha) and TCR beta-chain (TCR V beta) variable region repertoires of T-cells infiltrating the lungs tissue using a validated adaptor ligation polymerase chain reaction (PCR)-based microplate hybridization assay, comparing these to peripheral blood lymphocytes (PBL). We considered it important to perform TCR analysis from lung tissue in the earliest stage of IP because TCRs diversify with disease progression due to "determinant spreading" in which autoreactive T-cell responses, initiated by a single antigenic epitope, evolve into multispecific responses.

Results: The study with lung tissues of the initial stage of IP demonstrated substantial pulmonary CD3+ predominated T cell infiltrates. In both cases, patient A (early UIP pattern) and patient B (NISP pattern), most of the mononuclear cells were CD3+ T-cells, accompanied by a subtle infiltration of B-cells (CD20+), and a minimal number of monocytes (CD14+). Of infiltrating T-cells, most CD4+ than CD8+ cells (in the ratio of four to one) were noted in both patients. The usage of repertoires of TCR V alpha/beta in the lung differed from those in PBL, with certain TCR V gene families detected more frequently in lung tissue, suggesting a pivotal role for T cells in the pathogenesis of IP associated with PM. This is the first robust demonstration of selective TCR repertoire usage and its differential expression in lung tissue.

Background/Purpose: Inflammatory infiltrates of muscles in polymyositis patients are cytotoxic to autologous muscle cells in vitro via perforin-dependent mechanisms. **Reduction of MAIT Cell Frequency Associated with Reduced Cell Proliferation and Enhanced Cell Death in Systemic Lupus Erythematosus**

Asako Chiba, Naoto Tamura, Eri Hayashi, Ran Matsuda, Yoshibari Takasaki and Sachiko Miyake. Juntendo University School of Medicine, Tokyo, Japan.

**Background/Purpose:** Mucosal-associated invariant T (MAIT) cells are innate-like lymphocytes which are restricted by the MHC-related molecule-1 (MRC1) and express a semi-invariant TCR α chain: Vα7.2-Jα33 in humans and Vα19-Jα33 in mice. MAIT cells uniquely recognize microbial-derived vitamin B metabolites presented by MRC1. Like other innate-like lymphocytes, MAIT cells have been suggested to play both proinflammatory and regulatory roles in autoimmune models. Although MAIT cells are rare in mice, human MAIT cells have been suggested to play both proinflammatory and regulatory roles in autoimmune diseases. Previously we have revealed that the frequency of MAIT cells was reduced and reflected the disease activity in multiple sclerosis. In this study, we sought to investigate whether MAIT cells are involved in the pathogenesis of systemic lupus erythematosus (SLE).

**Methods:** Whole blood samples or peripheral blood mononuclear cells (PBMC) of SLE patients as well as healthy volunteers were stained with anti-human mononuclear antibodies (mAb) against CD3, γδ TCR, Vαα7.2TCR, CD161, CD45RA,CCR7, CD69, CD95 (FAS) and 7-AAD. MAIT cells were identified as CD3γδ TCR Vαα7.2 TCR CD161α T cells by FACsLSR Fortessa. In some experiments, costaining of intracellular active caspase-3 of MAIT cells was performed. MAIT cells and other T cell subsets were single-cell sorted by using FACs Aria II, and the usage of Vαα7.2-Jα33 TCR of single-cell sorted cells was examined by PCR. PBMC labeled with Cell Trace Violet Dye were stimulated with anti-CD3 mAb and anti-CD28 mAb or Fcγ receptors on activated naive CD4 T cells. Although the frequencies of naive cells were increased in lupus γδ T cells, most MAIT cells displayed an effector memory phenotype and there was no increase of naive cells among lupus MAIT cells.

**Conclusion:** This study demonstrates that the frequency of MAIT cells was significantly reduced in SLE. The increased cell death and reduced cell proliferation of activated MAIT cells were in part responsible for the decrease of MAIT cells in SLE. The limited recruitment of recent thymic emigrants of naive MAIT cells also contributed the profound reduction of these cells in SLE.

**To Live or Let Die... the Battle Between PD-1 and OX40 on SLE T Cells.**

Jule Kristine Laustsen1, Stein Greisen2, Bent Deleuran3 and Tue Kruse Rasmussen4.

1Aarhus University, Aarhus C, Denmark; 2Aarhus University Hospital, Aarhus, Denmark.

**Background/Purpose:** Programmed cell death 1 (PD-1) is a co-inhibitory receptor, which inhibits T cell proliferation and survival by inhibiting IL-2 signalling. By this PD-1 has been speculated as a key player in maintaining and restoring self-tolerance. In contrast, OX40 is a surface receptor that induces IL-2R expression and OX40 has been suggested to allow possible autoreactive effector T cells to develop into memory T cells. These two molecules could therefore represent two opposite sides of the balance in immune regulation - a balance crucial for maintaining peripheral tolerance. In systemic lupus erythematosus (SLE) this balance is disrupted, and disease progression is characterized by antibody production and autoreactive lymphocytes. In this study, we investigated cellular expression and soluble (s) levels of PD-1 and OX-40.

**Methods:** Plasma levels of sPD-1 and sOX40 from SLE patients (n=19) and healthy controls (HCs) (n=18) were quantified by ELISA. PBMCs from SLE patients and HCs were stained with monoclonal antibodies against PD-1, OX40, CD4, and CD8. Cells were gated based on flow cytometry. Skin biopsies from SLE patients and HCs were stained with anti-OX40 and anti-PD-1 antibodies and analyzed by confocal microscopy. Statistics were assessed by Mann-Whitney’s test, and Spearman’s ranked correlation. Data are expressed as median (IQR).

**Results:** In SLE patients, sPD-1 was significantly increased (445 pg/ml (319 pg/ml – 897 pg/ml)) compared to HCs (244 pg/ml (173 pg/ml – 343 pg/ml), p<0.001) and correlated positively with the SLE disease activity score SLEDAI (r=0.69, p=0.01). Soluble OX40 was decreased (7.3 pg/ml (7.3 pg/ml – 16.4 pg/ml)) compared with HCs (53.5 pg/ml (41.9 pg/ml - 72.5 pg/ml), p<0.001). Furthermore, the levels of sPD-1 and sOX40 were intercorrelated positively in SLE patients (r=0.59, p=0.005), which was not the case in HCs. Co-expression of PD-1 and OX40 was seen on (9.5%) CD4+ T cells in SLE compared with (5.2%) in HCs (p<0.01). Immunofluorescence revealed that PD-1 and OX40 co-expressing cells were present in SLE skin, further supporting that the same cell expresses both PD-1 and OX40 (Fig 1).

**Conclusion:** In this study, we show that T cells expressing both PD-1 and OX40 are increased in SLE, and that the levels of the soluble isoforms intercorrelate. We also show that sPD-1 correlates strongly with SLEDAI, suggesting sPD-1 as a marker of inflammation in SLE. The observed co-expression of the death receptor PD-1 and the survival receptor OX40, could in part explain why autoreactive effector T cells survive, despite receiving apoptosis signals, and help elucidate the lack of self-tolerance in SLE patients.

**FCγRIIIa Ligation in Human Peripheral CD4+ T-Cells Generate Th17-like Population.**

Anil K. Chauhan1, Terry Moore2 and Chen Chen3. 1Saint Louis University, St. Louis, MO, 2Saint Louis University, Saint Louis, MO.

**Background/Purpose:** Cytokines produced during Th17 response, IL-17A and IL-17F drive inflammation and autoimmunity. They also act as a bridge between adaptive and innate immunity. Immune deposits are formed in vascular sites in autoimmunity and often demonstrate the excessive presence of immune complexes (ICs) and activated complement products. ICs drive nephropathic changes in SLE. Thus, we examined whether these immune reactants can activate naive CD4+ T-cells to generate Th17-like cells. Furthermore to elucidate the mechanism by which ICs triggered the generation of Th17-like population, we also examined the presence of low affinity Fc-receptors on activated naive CD4+ T-cells.
Methods: Naive CD4+CD45RA+ T-cells obtained from SLE patients were activated using plate bound ICs (10 mg/ml) and soluble Csb5-2 (5 mg/ml) in the presence of anti-CD3 (0.25 mg/ml). Post activation cells were cultured in the presence of IL-1β (25 ng), IL-2 (10 ng), IL-6 (50 ng), IL-23 (25 ng), and TGF-β1 (10 ng) in each ml of RPMI. On day 9th culture soups were analyzed for cytokines and flow analysis was performed for IL-17A, IL-17F, IL-21, and IL-22. qRT-PCR was performed for IFN and Tnf IFN pathway genes were analyzed using qRT-PCR. IFN-arrays (Applied Biosystems).

Activated cells were analyzed for binding to labeled ICs and expression of fcrγ3a gene transcripts.

Results and Conclusion: Our results demonstrate that ICs via FcγR1IIa ligation on activated naïve CD4+ T-cells generate T-cell, like population. We observed increased expression of Th1 transcripts and statistically significant increase in IL-17A, IL-17F, IL-21, and IL-22 in the culture supernatants and an increase in cytokine producing population in flow analysis in response to ICs treatment. In addition IC mediated signal in CD4+ T-cells also generated an IFN-γ+ population. ICs and complement provided a co-stimulatory signal that was strong and divergent from the traditional CD28 co-stimulatory signal. CD4+ T-cells activated anti-CD3+ICs+Csβ-9 induced expression of fcrγ3a transcripts and membrane FcγR1IIa protein. These activated cells showed statistically significant increase in binding to labeled ICs and ANG in flow analysis. These results for the first time demonstrate a possible role for FcγR1IIa in the generation of T-cell, like cells. Our IFN array analysis also showed increase in type 1 IFN genes. In autoimmune disease a co-operation between type 1 IFNs and Th17 has been observed. Our data suggest that both of these responses are driven by ICs and complement in CD4+ T-cells. Generation of Th17, like population and IFN-γ producing cells will contribute to the development of lupus nephritis, which could occur locally in the kidney. These findings are important in that the activating membrane co-stimulatory signal from CD28 and ICOS are counteracted by CTLA4 and PD1 inhibitory signal during immune contraction. An activating signal from ICs and complement in immune contraction can tip the balance in favor of activating signal that may lead to breakdown of peripheral tolerance. Thus the data present identifies a new pathway by which ICs and complement will drive the autoimmune pathology.

Th1 and Th17 Cytokines Drive Takayasu Arteritis Inflammation. David Saadoun1, Marion Garrido2, Cléo Comarmond3, Anne-Claire Desbois4, David Klatzman5, Pierre Fourret6, Philippe Cluzel7, Julien Gaudric8, Fabien Koskas9, and Patrice Cacoub10.

Background/Purpose: Takayasu arteritis (TA) is a large-vessel vasculitis inducing damage of the aorta and its branches. Glucocorticoids remain the gold standard of therapy in TA. However, the nature of T cell driving vascular inflammation and the effects of glucocorticoids on the systemic components of TA are not understood.

Methods: T cell homoeostasis and cytokines production were analyzed in peripheral blood and aorta inflammatory lesions using Luminex, flow cytometry, and immunohistochemistry analysis. The study included 41 TA patients fulfilling the ACR criteria [17 active (aTA) and 24 in remission (rTA)]. 30 giant cell arteritis (GCA) patients (disease control) and 20 age and sex-matched controls.

Results: We first demonstrated the promotion of Th1 and Th17 responses that correlates with TA activity. We determined whether serum from TA patients is able to modulate T cell differentiation in healthy controls. The addition of serum from active TA patients in sorted CD4+ T cell culture of healthy donors induced a significant production of IFN-γ and IL-17A. We demonstrated the strong expression of IFN-γ, and IL-6 producing T cells within vascular inflammatory infiltrates of TA. Glucocorticoid therapy were associated to decreased circulating Th1 cytokines with significantly lower IL-2 (mean±SEM: 2812.6±690.1 vs. 7228±1356 pg/ml, p=0.0196), IFN-γ (1437±367.3 vs. 7124±1818 pg/ml, p=0.0191) and TNF-α (643.3±106.4 vs. 1438±196.6 pg/ml, p=0.01) in steroid treated TA compared to steroid free TA patients, respectively. However, glucocorticoids essentially left unaffected Th17 cytokines (i.e. IL-1b, IL-6, IL-17 and IL-23).

Conclusion: We provided the first evidence that Th1 and Th17 immunity seems to be important in driving TA inflammation, both systemically and in the blood vessels. In addition, one of these pathways was amendable to glucocorticoid-mediated suppression. Glucocorticoids are associated to decrease Th1 cytokines and spared Th17 cytokines in TA.

Massive Ex Vivo Expansion of Functionally Stable Beohct's Patient-Derived Regulatory T Cell Clones. Johannes Nowatzky, Olivier M. Manches, Yusuf Y. Yazici and Juan Lafaille. New York University School of Medicine, New York, NY.

Background/Purpose: A leptime transfer of regulatory T cells (Treg) is a promising strategy for the treatment of human autoimmune diseases. Most currently tested approaches focus on the polyclonal expansion of human Th17. Our results demonstrate that ICs via FcγR1IIa ligation on activated naïve CD4+ T-cells generate T-cell, like population. We observed increased expression of Th1 transcripts and statistically significant increase in IL-17A, IL-17F, IL-21, and IL-22 in the culture supernatants and an increase in cytokine producing population in flow analysis in response to ICs treatment. In addition IC mediated signal in CD4+ T-cells also generated an IFN-γ+ population. ICs and complement provided a co-stimulatory signal that was strong and divergent from the traditional CD28 co-stimulatory signal. CD4+ T-cells activated anti-CD3+ICs+Csβ-9 induced expression of fcrγ3a transcripts and membrane FcγR1IIa protein. These activated cells showed statistically significant increase in binding to labeled ICs and ANG in flow analysis. These results for the first time demonstrate a possible role for FcγR1IIa in the generation of T-cell, like cells. Our IFN array analysis also showed increase in type 1 IFN genes. In autoimmune disease a co-operation between type 1 IFNs and Th17 has been observed. Our data suggest that both of these responses are driven by ICs and complement in CD4+ T-cells. functionally reported different phenotypes within the expanded CD4+ TEM cell population in peripheral blood of GPA-patients.

**Methods:** Peripheral blood of 43 GPA-patients in remission and 16 healthy controls (HCs) was stained immediately after blood withdrawal with fluorochrome-conjugated antibodies for cell surface markers (CD3, CD4, CD45RO) and chemokine receptors (CCR4, CCR6, CCR7, CRTh2, CXCR3) followed by flow cytometry analysis. Positively and negatively stained populations were calculated by dot plot analysis, determined by the appropriate isotype controls. Expression patterns of chemokine receptors CXCR3, CXCR4, CCR6, CCR7, CRTh2, CXCR3 were used to distinguish Th1, Th2, Th17 and Th1/17 cells, respectively.

**Results:** The percentage of CD4+ TEM (CD3+CD4+CD45RO+CCR7+) cells was significantly increased in GPA-patients in remission compared to HCs (median 41.93% vs 31.52%). Chemokine receptor co-expression analysis within the CD4+ TEM cell population demonstrated similar percentages of Th1 and Th2 cells between GPA-patients and HCs. Interestingly, the analysis revealed a significant decrease in the frequency of Th1/17 cells (median 9.28% vs 16.53%) with a concomitant significant increase in the Th17 cells (median 21.14% vs 16.93%) in GPA-patients compared to HCs. However, differences between these CD4+ TEM cell subsets were not related to generalized or localized disease, ANCA positivity at the time of inclusion, nor to immunosuppressive treatment regimen.

**Conclusion:** Based on chemokine receptor co-expression analysis we demonstrate an aberrant distribution in the CD4+ TEM cell compartment in GPA-patients. The identification of different phenotypes within the expanded CD4+ TEM cell population revealed a distinction between Th1/17 cells and Th17 cells. Interestingly, it has been described that the functional and molecular signature of Th1/17 cells is associated with a strong polarization of this subset and may be important in mediating chronic inflammation. Analyzing the migration capacity of Th1/17 cells might reveal their distinct tissue homing characteristic to inflamed lesions in GPA-patients.

**B55β Regulates T Cell Survival through the Modulation of AKT during Cytokine Deprivation.** Jose C. Crispin1, Sokrats A. Apostolis1, Neri Rodriguez Rodriguez1, Tran Nguyen2, and George C. Tsokos1.

**Background/Purpose:** The abundance of cytokines controls the length of immune responses through poorly defined mechanisms. B55β is a molecule that triggers apoptosis in activated T cells when cytokine levels decrease. T cells from a subset of patients with systemic lupus erythematosus (SLE) exhibit resistance to apoptosis that is associated to failure to express B55β. The aim of this study was to determine the molecular mechanisms through which B55β controls the survival of activated T cells.

**Methods:** Most experiments were performed in human primary T cells obtained from healthy donors. MCF7 cells were used in some experiments. T cells were activated with anti-CD3 and anti-CD28 (1 μg/mL). After day 3, fresh RPMI and IL-2 (100 U/mL) were replenished every 48 hours. Apoptosis was quantified in T cell lysates by ELISA. AKAP79 mutants deficient for association to PKA (ΔPKA-AKAP79), PKC (ΔPKC-AKAP79) and calcineurin (ΔCN-AKAP79) were generated with QuickChange Site Directed Mutagenesis kit and confirmed by sequencing. Jurkat T cells were transfected with dual promoter pRRL-AKAP79/GFP- or control pRRL-GFP-expressing lentiviruses. For functional assays, T cells were stimulated with plate-bound anti-CD3 and soluble anti-CD28 antibodies or tPA/monocyte. RNA was isolated, IL2 transcripts quantified by quantitative real-time PCR (qPCR) and results normalized to unstimulated control. qPCR and western blotting. Statistical differences between groups were analysed by ANOVA and non-parametric Mann-Whitney U test, using GraphPad Prism software.

**Results:** IL2 transcription induced by anti-CD3/CD28 stimulation was not significantly different between SLE (n=6) and HC (n=6) T cells. However, a negative correlation between levels of AKAP79 protein and levels of AKAP79 expression and was reduced by IL2 deprivation but that the pathway is not uniformly downregulated. mTORC1 and its substrates were mostly not affected whereas other AKT substrates, in particular the pro-apoptotic protein BAD and the transcription factors Foxo1 and 3a, were activated by dephosphorylation. Accordingly, induction of pro-apoptotic genes regulated by Foxo factors was observed. Further experiments confirmed that B55β overexpression activates the Foxo factors inducing the upregulation of pro-apoptotic genes, in particular Noxa, Puma and HRK.

**Conclusion:** B55β is a key regulator of AKT. Upon its induction by IL-2 deprivation, it causes AKT dephosphorylation triggering programmed cell death. We report for the first time the induction of apoptosis associated to dephosphorylation of AKT S473. Simultaneous phosphorylation status of 18 members of the pathway using an intracellular signaling array. The results confirmed that AKT is dephosphorylated by IL-2 deprivation but that the pathway is not uniformly downregulated. mTORC1 and its substrates were mostly not affected whereas other AKT substrates, in particular the pro-apoptotic protein BAD and the transcription factors Foxo1 and 3a, were activated by dephosphorylation. Accordingly, induction of pro-apoptotic genes regulated by Foxo factors was observed. Further experiments confirmed that B55β overexpression activates the Foxo factors inducing the upregulation of pro-apoptotic genes, in particular Noxa, Puma and HRK. Our results demonstrate a novel mechanism of how AKT is regulated in activated T cells in response to cytokine abundance.

**Disclosure:** J. C. Crispin, None; S. A. Apostolis, None; N. Rodriguez Rodriguez, None; T. Nguyen, None; G. C. Tsokos, None.

**Association of A Kinase Anchoring Protein-79 (AKAP79) to PKC mediates Inhibition of IL2 Transcription and Erk Activation in T Cells.**

Gabriel Criado, Marı́a J. Pérez-Lorenzo, Marı́a Galindo, José L. Pablos and Abel Suarez-Fuego. Instituto de Investigación Hospital 12 de Octubre (i+12), Madrid, Spain.

**Background/Purpose:** A-Kinase anchoring Protein AKAP79 associates to and regulates the activity of PKA, PKC and calcineurin, key regulators of T cell activation. We have previously described that AKAP79 is overexpressed in T cells from systemic lupus erythematosus lupus patients and inhibits IL2 transcription in Jurkat T cells (Criado et al., A & R 63 (Suppl10): S5916). In the present study, we aim to analyze the effect of AKAP79 levels on IL2 production in SLE and normal T cells and characterize the role of the association to PKA, PKC and calcineurin in T cell activation and IL2 transcription.

**Methods:** T cells were isolated by negative selection from SLE patients and healthy controls (HC). RNA was purified, retrotranscribed to cDNA and levels of AKAP79 and β-actin transcripts were quantified by quantitative real-time PCR using Sybr Green technology. AKAP79 protein expression was quantified in T cell lysates by ELISA. AKAP79 mutants deficient for association to PKA (ΔPKA-AKAP79), PKC (ΔPKC-AKAP79) and calcineurin (ΔCN-AKAP79) were generated with QuickChange Site Directed Mutagenesis kit and confirmed by sequencing. Jurkat T cells were transfected with dual promoter pRRL-AKAP79/GFP- or control pRRL-GFP-expressing lentiviruses. For functional assays, T cells were stimulated with plate-bound anti-CD3 and soluble anti-CD28 antibodies or tPA/monocyte. RNA was isolated, IL2 transcripts quantified by quantitative real-time PCR (ΔqPCR) and results normalized to unstimulated control. Statistical differences between groups were analysed by ANOVA and non-parametric Mann-Whitney U test, using GraphPad Prism software.

**Results:** IL2 transcription induced by anti-CD3/CD28 stimulation was not significantly different between SLE (n=6) and HC (n=6) T cells. However, a negative correlation between levels of AKAP79 protein and induction of IL2 transcription was found in T cells, regardless of their origin (R2 = 0.53, p=0.0076). This was confirmed in Jurkat T cells by transduction with different amounts of AKAP79 (R2 = 0.57, p=0.03, n=8). Complementation of anti-CD3/CD28 stimulation by tPA, but not monocyte, restored IL2 transcription in Jurkat cells overexpressing AKAP79, suggesting that inhibition of PKC by AKAP79 was responsible for the observed reduction of IL2 transcription. Consistent with this interpretation, overexpression of ΔPKC-AKAP79 partially rescued IL2 transcription when compared to WT-AKAP79 but ΔPKA-AKAP79 and ΔCN-AKAP79 had no significant effect (GFP: 11.59 +/- 2.21, AKAP79: 8.67 +/- 0.01, ΔPKC-AKAP79: 4.86 +/- 1.24, ΔPKA-AKAP79: 0.73 +/- 0.29, ΔCN-AKAP79: 0.88 +/- 0.35). Likewise, analysis of the kinetics of Erk activation in response to antiCD3/CD28 showed that Erk activation was blocked by AKAP79 overexpression and was recued by ΔPKC-AKAP79.

**Conclusion:** Overexpression of AKAP79 inhibits IL2 transcription and Erk activation in a PKC-dependent manner. Thus, targeting AKAP79-PKC interaction could provide a therapeutic approach to modulate T cell activation.

Female Specific Increase in T Cell Glycosylation in Lupus. Gabriela Gorelik and Bruce Richardson. University of Michigan, Ann Arbor, MI.

**Background/Purpose:** Systemic Lupus Erythematosus (SLE) is an autoimmune inflammatory disease characterized by altered T cell signaling. SLE is characterized by epigenetic mechanisms that cause hypomethylation of the inactive X-chromosome predisposing females to the disease, and a global T cell DNA hypomethylation, which causes overexpression of immune-related genes.

**Conclusion:** We demonstrate that SLE patients have reduced IL-21 signaling capacity, decreased miR-155 levels, and increased SOCS1 levels compared to HCs. The reduced IL-21 signaling in SLE could be rescued by overexpression of miR-155, suggesting an important role for miR-155 in the reduced IL-21 signaling observed in SLE.

---

**Background/Purpose:** The voltage-gated potassium channel Kv1.3 is a novel target for the treatment of autoimmune disorders including psoriatic and rheumatic diseases. Shk-186 is an exquisitely specific, highly potent peptide inhibitor of Kv1.3 on activated effector memory T cells that has just entered clinical development. Here, we report on Shk-186’s safety and tolerability in phase I trials and on the evaluation of its therapeutic potential in an autoimmune kidney disease model.

**Methods:** To evaluate the safety, tolerability and pharmacokinetics (PK) of Shk-186, we conducted single ascending dose and multiple ascending dose double-blind, placebo-controlled phase I trials in healthy volunteers. In the single ascending dose trial, individuals were given increasing doses of Shk-186 subcutaneously and characterized after a single dose of drug; in the multiple ascending dose trial, individuals were given 9 doses of drug twice weekly for 4 weeks and characterized throughout. To investigate Shk-186’s potential therapeutic application in autoimmune kidney disease, we evaluated the drug in a glomerular basement membrane animal model of autoimmune glomerulonephritis. Moreover, we have begun evaluating peripheral blood and urine samples from patients with autoimmune kidney disease for expression of Kvl3 and production of cytokines in the presence and absence of Shk-186.

**Results:** Shk-186 was well tolerated with no serious adverse events reported. PK analysis revealed that the doses and dose regimens evaluated provided drug exposure in plasma surpassing the predicted therapeutic range based on therapeutic drug exposures in preclinical models of disease. Supporting the therapeutic potential of Shk-186 to treat chronic autoimmune kidney diseases, we showed that Shk-186 could lower kidney disease parameters such as urine protein and creatinine in a model of autoimmune glomerulonephritis, as well as significantly reduced histopathological changes associated with disease such as crescent formation and inflammatory cell infiltrate. Ex vivo immunophenotyping and functional studies of blood and urine from autoimmune kidney disease patients showed that Kvl3 is present in effector memory T cells.

**Conclusion:** This first-in-human clinical trial suggests that Shk-186 is a well-tolerated drug when given at doses expected to provide a therapeutic benefit. In addition to previously described indications where Kvl3 has been implicated including multiple sclerosis and rheumatoid arthritis, we provide evidence to support extending its therapeutic scope to the treatment of chronic kidney autoimmune diseases.

**Microrna-155 Suppresses IL-21 Signaling and Production in Systemic Lupus Erythematosus.** Tue K. Rasmussen, Thomas Andersen, Rasmus Bak, Gloria Y. u, Kristian Steengaard-Petersen, Jacob G. Mikkelsen, Paul J. Utz, Christian Holm and Bent Deleuran. 1Arhus University, Aarhus C, Denmark, 2Stanford University School of Medicine, Stanford, CA, 3Aarhus University Hospital, Aarhus, Denmark.

**Background/Purpose:** IL-21 is a key regulator of B cells functions and autoantibody production and is mainly produced by follicular T help cells. The purpose of this study is to investigate the signaling capacity of interleukin (IL-21) in T and B cells and assess its possible regulation by microRNA-155 and its target gene suppressor of cytokine signaling 1 (SOCS1) in systemic lupus erythematosus (SLE).

**Methods:** The signaling capacity of IL-21 was quantified by stimulating PBMCs with IL-21 and measuring phosphorylation of pSTAT3 in CD4+ T cells, B cells, and NK cells. Induction of miR-155 by IL-21 was investigated by stimulating purified CD4+T cells with IL-21 and measuring miR-155 expression levels. The functional role of miR-155 was assessed by overexpressing miR-155 in PBMCs from SLE patients and HCs and measuring its effects on STAT3 and IL-21 production in CD4+ and CD8+ T cells.

**Results:** Induction of pSTAT3 in CD4+ T cells in response to IL-21 was significantly decreased in SLE patients compared to HCs (p<0.0001). Further, expression levels of miR-155 were significantly decreased and SOCS1 correspondingly increased in CD4+ T cells from SLE patients. Finally, overexpression of miR-155 in CD4+ T cells increased STAT3 phosphorylation in response to IL-21 treatment (p<0.01) and differentially increased IL-21 production in SLE patients compared to HCs (p<0.01).

**Conclusion:** We demonstrated that SLE patients have reduced IL-21 signaling capacity, decreased miR-155 levels, and increased SOCS1 levels compared to HCs. The reduced IL-21 signaling in SLE could be rescued by overexpression of miR-155, suggesting an important role for miR-155 in the reduced IL-21 signaling observed in SLE.

**Disclosure:** T. K. Rasmussen, None; T. Andersen, None; R. Bak, None; G. Yiu, None; N. K. Steenbergs-Petersen, None; J. G. Mikkelsen, None; P. J. Utz, None; C. Holm, None; B. Deleuran, None.

**SHP-1 Regulates the Activation Threshold of INKT Cells.** Meng Zhao and Mitchell Kronenberg. UC-San Diego, La Jolla, CA, La Jolla Institute for Allergy and Immunology, La Jolla, CA.
**Background/Purpose:** Autoimmune invariant Natural Killer T (iNKT) cells have been implicated in several rheumatic diseases, including Systemic lupus erythematosus and Rheumatoid arthritis. iNKT cells are a unique subpopulation of lymphocytes that recognize glycolipids presented by CD1d, and that express an invariant T cell receptor (TCR). As a result of activation, iNKT cells secrete copious amount of cytokines, including IFN-γ, IL-4, IL-17 and IL-21 and they mediate immune responses in various pathological conditions. Although several potential lipid self-antigens for iNKT cell development and activation have been identified, the mechanism by which iNKT cells react to CD1d-self-antigen is not understood yet. Our discoveries therefore will help identify novel drug targets for potential translational intervention in patients with SLE, RA and other autoimmune diseases in which abnormal activation of iNKT cells is observed.

**Methods:** In detecting autoreactivity, instead of iNKT cell hybridomas that have many limitations, we will use primary cultured mouse iNKT cells. Sorted as αβLCer-CD1d tetramers “TCRβ+” iNKT cells grow exponentially in vitro, and can be transduced by retroviruses in order to modulate differential expressions of important regulators. Microarray was carried out to identify new regulators of iNKT cell autoreactivity.

**Results:** Our data show that the cultured iNKT cells have a greatly increased sensitivity to CD1d-lipid complexes derived from multiple sources, including soluble CD1d molecules produced in insect or mammalian cells, CD1d transfected cultured cells, and bone marrow-derived DCs. APCs that express a tail-deleted form of CD1d have a strongly diminished ability to stimulate the iNKT cell lines, indicating that the lines, like their primary cell counterparts in vivo, recognize auto-Ags loaded onto CD1d in endo/lysosomal compartments. Our results show that the iNKT cell lines preferentially respond to specific epithelial cells that were described previously when compared to the closely related homologs, despite their very different structures. Microarrays comparing the expression profiles of cultured and freshly isolated iNKT cells identifies SHP1/PTPN6, a tyrosine phosphatase that regulates TCR signaling, is down regulated in the iNKT cell lines. Reconstitution of the lines with the wild type but not the catalytically inactive SHP1 decreases the auto reactivity of the iNKT cell lines.

**Conclusion:** We hypothesize that iNKT cell TCR is intrinsically autoreactive, and instead of requiring a specific autoantigen, many autologous Ags are capable of stimulating iNKT cells. The threshold of activation for iNKT cells are controlled during development and immune responses through key regulators, so that in the situation when this threshold is lowered, iNKT cells are activated by common lipid antigens that are present in the DP thymocytes or APCs. In the present study, taking advantage of a new system, we show the autoreactivity of polyclonal iNKT cells and we discover the protein tyrosine phosphatase SHP1 (Ptpn6) is a critical regulator of the activation threshold of iNKT cells.

**The Role of Fli1 in Lupus T Cell Function and Nephritis.** Thirumagal Thyagarajan, Ivan Molano and Tamara K. Nowling. *Medical University of South Carolina, Charleston, SC; Medical University of South Carolina and Ralph H. Johnson VA Medical Center, Charleston, SC.*

**Background/Purpose:** The Ets factor Fli1 is implicated as a key modulator of lupus disease expression. Over-expressing Fli1 in healthy mice, results in the development of an autoimmune kidney disease similar to that observed in lupus. Lowering the global levels of Fli1 in two lupus mouse models significantly improved kidney disease and prolonged survival. Lowering the levels of Fli1 in hematopoietic cells in MRL/lpr lupus mice resulted in significantly improved kidney disease. We recently demonstrated that lowering the global levels of Fli1 in the MRL/lpr lupus model has specific effects on T cells, including reducing their activation and IL-4 production when stimulated through the T cell receptor. We further showed that this was likely a result of decreased glycosphingolipid (GSL) metabolism, specifically decreased Neuraminidase1 (Neu1) expression and activity and decreased lactosylceramide (LacCer) in T cells. GSls are a heterogeneous class of lipids in the sphingolipid family that play a role in the regulation of cellular processes. LacCer is a GSL to which sialic acid residues are added by ganglioside synthases to generate ganglio- side and other GSLs in the GSL synthetic pathway. Sialic acids are then removed by NEUs from gangliosides in the GSL catabolic pathway. Lipids with distinct chain lengths are thought to possess distinct biological activities. We now demonstrate that lowering Fli1 levels significantly decreases the number of CXCR3+ T cells, T cell migration to the kidney and GSL metabolism in the kidney of MRL/lpr lupus prone mice.

**Methods:** Kidney and/or spleen were harvested from non-splenectomized 11, 14 and 18 week-old MRL/lpr Fli1+/+ and Fli1−/− mice. Kidneys and/or T cells isolated from spleen by negative selection were analyzed by flow cytometry. Supercritical Fluid Chromatography coupled with tandem mass spectrometry was performed on kidney cortex homogenates. Gene expression was analyzed by real-time RTPCR on RNA isolated from kidney cortex. Mx48-assisted laser desorption/ionization-imaging mass spectrometry (MALDI-IMS) imaging and immunohistochemistry (IHC) for LacCer was performed on frozen kidney sections.

**Results:** LacCer levels, which are elevated in the kidneys of MRL/lpr mice controlled to controls, are significantly reduced by 50% in age-matched MRL/lpr mice that are heterozygote for Fli1 (Fli1+/−). This reduction in LacCer expression is observed across the kidney using MALDI-IMS. Although Neul expression and Neu activity is decreased in T cells, their levels are unchanged in the kidney of Fli1+/− compared to Fli1+/+ MRL/lpr mice. The percentage of T cells expressing CXCR3 is significantly reduced by ~30% in Fli1−/− compared to Fli1+/+ MRL/lpr mice and the percentage and overall number of T cells in the kidney are significantly reduced by ~50%.

**Conclusion:** Our results demonstrate that one mechanism by which reducing Fli1 levels may be protective in lupus kidney disease is to decrease GSL metabolism in T cells, reducing T cell activation, production of IL-4, expression of CXCR3, a receptor shown to be important in T cell migration.
to the kidney in lupus, and migration to the kidney. This likely contributes to the decreased inflammation and GSL metabolism in the kidney and improved kidney disease of MRL/lpr F1/+/-- mice.

**Polymorphisms in the Slam Family of Molecules Play a Role in the Development and Function of Invariant Natural Killer T Cells in New Zealand Black Mice.** Yuryi Baglaenko,1 Kieran Mainion,1 Nan-Hua Chang2 and Joan E. Wither2.1 University of Toronto, Toronto, ON, 2Toronto Western Research Institute, Toronto Western Hospital, Toronto, ON, 3Toronto Western Research Institute, Toronto Western Hospital, University of Toronto, ON, Toronto.

**Background/Purpose:** The family of signaling lymphocyte activating molecules (SLAM) have been shown to play a key role in the development of autoimmunity in spontaneous and induced mouse models. Previous work by others has shown that expression of two SLAM family members, CD150 and Ly108, plays a critical role in the development of Natural Killer T (NKT) cells, an innate-like semi-invariant population of lymphocytes, which quickly respond to lipids presented on non-classical MHCs. However, the impact of SLAM polymorphisms on NKT function is less clear. The aim of this study was to characterize both the development and function of NKT cells in B6 congenic mice with an NZB chromosome 1 interval that is known to have polymorphisms in the SLAM family of molecules.

**Methods:** NKT development and marker expression were examined by flow cytometry of de novo splenocytes and thymocytes. NKT cell function was examined by in vivo stimulation with 2μg of αGalCer, injected intravenously. Production of IFN-γ and IL-4 was measured by intracellular flow cytometry. Bone marrow derived dendritic cells (BMDCs) were generated by 7–10 day culture with recombinant human FLT3 ligand.

**Results:** Congenic mice had significantly fewer splenic NKT cells when compared to B6 controls. However, NKT cell frequencies in the thymus did not differ. The frequency of double positive thymocytes, critical for homotypic interactions between NKT cell precursors, was also unchanged. In support of previous findings, cell surface expression of SLAM family members on this cell population was altered. When compared to control animals, NZB congenic mice had significantly decreased expression of positive signaling Ly108 and CD150 molecules and increased expression of the negative SLAM signaling molecule, Lyl9. Since NKT cells have been shown to play a role in autoimmunity through production of cytokines such as IL-4 and IFN-γ, the capacity of these cells to secrete cytokines was assessed. Upon stimulation with αGalCer, the prototypic NKT cell stimulating lipid, NKT cells from NZB congenic mice produced significantly less IL-4 and IFN-γ when compared to control mice. Consistent with this being the result of the SLAM polymorphisms, analysis of subcongenic NZB strains with shorter chromosome 1 intervals revealed that both of these phenotypes localized to a small region between 171–177Mb containing the SLAM family. To determine whether the reduced NKT cytokine production in NZB congenic mice was due to altered antigen presentation or impaired NKT cell function, adoptive transfer experiments were conducted with αGalCer pulsed BMDCs from control or congenic mice. The results revealed that injection of BMDCs generated from either strain could equivalently stimulate IL-4 and IFN-γ production by NKT cells in control animals, whereas injection of control BMDCs into NZB congenic mice resulted in impaired production of these cytokines.

**Conclusion:** These data suggest that polymorphisms in the SLAM family result in reduced peripheral NKT cell numbers and an intrinsic NKT cell functional defect.

**CD27 Is a Key Regulator of T Cell Responses.** Michael Scully1, Nicole Wunderler2, Holger Babbe2, Yevgeniy Orlovsky3, Galina Osmolova3, Ann Ca4, Health Guay5, Jacqueline Benson6 and Tatiana Ort3.1 Immunology Research, Janssen Research and Development, LLC, Spring House, PA, 2Toronto Western Research Institute, Toronto Western Hospital, Toronto, ON, 3Toronto Western Research Institute, Toronto Western Hospital, University of Toronto, ON, Toronto.

**Background/Purpose:** CD27 is a member of the TNF superfamily of receptors that is expressed on a majority of natural killer (NK) cells, T cells, memory B cells and antibody-secreting plasma cells in humans. CD70 is the only known ligand for CD27 and is transiently expressed on activated dendritic cells, B cells and T cells. Much of our understanding of the immunological role of CD27 comes from studies with mouse models, which suggest that CD27 is a key regulator of NK cell, T cell and B cell responses. Here, we used an in-house generated neutralizing, antagonistic antibody to evaluate the role of CD27 in regulating human and primate immune responses using in vitro and in vivo models.

**Methods:** To examine the role of CD27 in immune cell biology, we generated a neutralizing, antagonistic and non-depleting human anti-human CD27 antibody. To assess the contribution of CD27 signaling to human immune responses in vitro, we examined the effects of CD27 blockade on Ig-production by B cells, proliferation of naïve CD4+ T cells and cytokine production by healthy volunteer PBMCs in vitro. To understand the role of CD27 on immune responses in vivo, we examined the effects of CD27 blockade on T and B cell responses in a cynomolgus monkeyDelayed Type Hypersensitivity (DTH) model. To further explore the contribution of CD27 to human T cell responses in vitro, we examined the effects of CD27 blockade on human T cell engraftment in the NSG (NOD/Scid IL-2Rγ−/−) human CD45+ peripheral blood cell → mouse GVH model.

**Results:** We found that neutralizing the CD27 pathway inhibited CD70-induced Ig-secretion by activated human B cells, whereas blockade of CD27 in an autologous T cell:B cell co-culture model did not impact Ig-secretion in vitro (despite expression of CD27 on cells in this system). Treatment with an anti-CD27 antibody dose-dependently attenuated CD70-mediated induced proliferation of primary human CD4+ T cells and decreased the production of pro-inflammatory cytokines by healthy control PBMCs in vitro. Treatment with an anti-CD27 antibody reduced human CD45+ CD4+ and CD8+ T cell numbers in the spleen and peripheral blood of host mice in the human cell → NSG mouse GVH model. Blockade of CD27 reduced T cell infiltration into the challenge site in response to a neo-antigen, but did not impact antigen-specific antibody titers in a cynomolgus monkey DTH model.

**Conclusion:** These data demonstrate that CD27 can promote Ig-production by human B cells, but may play a redundant role in some types of B cell responses. In contrast, CD27 appears to play a critical role in the generation of both CD4+ and CD8+ T cell responses. These data suggest that the CD27 pathway modulates the activity of multiple human immune cell types, and that blockade of the CD27 pathway may present a novel therapeutic strategy for the treatment of immune mediated diseases.

**MI-RNA Profile of Active Vascular BEHÇET’S Patients.** Ahmet Mesut Onal1, Ozan Gerenli1, Bıyımnüş Canıası2, M. Mustafa Ulası3, Gezmis Kimyon4, Ayaz Pehlivan5 and Serdar Oztuzcu6.1 Gaziantep University School of Medicine, Gaziantep, Turkey, 2Gaziantep UniversitySchool of Medicine, Gaziantep, Turkey, 3Uludag University, School of Medicine, Bursa, Turkey.

**Background/Purpose:** Behçet’s Disease (BD) is a systemic vasculitis that predominantly presented with oral aphthous ulcers and additionally at least two of the following findings like genital ulcers, eye involvement, skin lesions and pathergy reaction. Vascular involvement is devastating face of BD and thrombosis of the arterial and venous system and aneurismatic arterial disease is not rare. The flares are the typical nature of BD and the pathology of the disease is mostly constructed on vasculitis. However the satisfied mechanism of BD remains unknown. We herein tried to evaluate the micro RNA (miRNA) behavior in BD.

**Methods:** Eighty-five BD patients were enrolled in to the study group, which were divided to 3 groups of 20–25 and 25 with active vascular disease, active mucocutaneous disease and patients with at least 6 months remission, respectively. A additional 25 volunteers were the healthy controls and the 4 of the groups have no difference in the characteristics. The whole study population was male, due to difficulties of finding active women BD patients.
Serum samples were analyzed for miRNA with PCR assay and the data were analyzed statistically. A clive vascular patients had significantly higher CRP and ESR results than active mucocutaneous ones and they both had higher levels than remission and healthy groups.

Results: There was no difference for any miRNA between BD patients with remission and healthy controls. The comparison of active BD patients and healthy controls revealed lower levels of miR-17-5p, miR-451A, miR-106b-5p, miR-19b-3p, miR-26b-5p, miR-93-5p, miR-250b, miR-25-3p in the disease activity, miR26b-5p was found lower only in mucocutaneous plasma (from HC, iBD or aBD). Gene expression for the five NADPH-oxidase substrates was determined by luminol/lucigenin luminescence with or without stimulation with AB (Table 1) and NADPH-oxidase expression (Table 2) was higher after stimulus with aBD or iBD plasma. PBMC displayed equivalent results. Resting and pathogen-stimulated phagocytes presented equivalent O2⁻/H2O2 production and NADPH-oxidase expression. NET formation was constitutive and NADPH-oxidase expression. NET formation was constitutively increased in aBD or iBD plasma, compared to HC neutrophils (Table 3). Similarly, neutrophils from aBD and iBD produced more extensive NET than neutrophils from HC (Table 3). We aimed to search the relation among levels of visfatin with activity of BD.

Background/Purpose: It’s a known fact that serum levels of the tumor necrosis factor alpha (TNF-α) interleukin-6 (IL-6) and other proinflammatory cytokines which are released from the adipose tissue are increased in Behçet’s disease (BD). In BD adipose tissue is not a passive energy depot, it is an active endocrine organ and releases adipokines. Visfatin is one of them. Visfatin is related to TNF-α and IL-6, IL-1 beta, co-stimators like CD40, CD54 and CD 80 and endothelial I CAM-1 and ICAM-2. We aimed to search the relation among levels of visfatin with activity of BD.

Methods: 60 BD (30 patients were in active state and 30 were in remission) patients diagnosed according to The Criteria of Working Group on International BD and 20 health subjects as controls were involved in to the study. The study of groups detected visfatin levels were compared among groups.

Results: Visfatin levels were significantly higher in both group of patients compared to the control group (both p<0.001). Serum visfatin levels in patients with active than in inactive patients were found statistically significantly higher (p<0.001). The same way in all cases statistically significant correlation between visfatin and CRP (p<0.001) and visfatin and ESR (p<0.001). Only according to the symptoms of the patients in the active group compared to visfatin levels in patients with genital aphth visfatin levels, a statistically significantly higher than in patients without genital aphth were detected (p<0.001).

Conclusion: Serum visfatin levels in patients with active and inactive causes are higher than the control group; visfatin proinflammatory cytokines have a role in chronic inflammatory reaction, and to sustain the cellular expression of the inflammatory stochiomer which induced that conclude or be due to different reasons.

Background/Purpose: Thrombosis occurs in 20% of patients with Behçet’s Syndrome (BS) and leads to significant morbidity. There is no robust association between thrombosis in BS and the presence of hereditary thrombophilia or raised inflammatory markers. It remains a challenge to distinguish those at risk of thrombosis potentially requiring aggressive preventative therapy and those whose therapy can be reduced. There is a clear need to develop biomarkers for diagnosis and risk management in BS.

Results: MPs were prepared following venepuncture of 88 BS patients who fulfilled International Study Group Criteria for diagnosis, 21 of whom had a history of thrombosis, and 39 healthy controls (HC). MPs were identified using flow cytometry by gating for particles less than 1 μm in size and staining positively with Annexin V, which binds PS, giving a total MP count. Antibodies to CD14 (monocytes), TF, CD62P (platelets), CD144 (endothelial cells) and CD66b (neutrophils) were used to identify cellular markers. MPs were measured using calibrated automated thrombography, allowing analysis of the thrombotic potential of MPs.

Conclusion: MPs are found in higher numbers in BS patients than in HCs, and in TBS patients compared to NTBS patients. MPs are associated with thrombosis in Behçet’s Syndrome (BS).

The Clinical Course of Acute Deep Vein Thrombosis of the Legs in Behcet’s Syndrome. M. Elkele Mikellioglu1, Y. esim Ozguler2, Serdal Ugurlu3, Firat Cetinkaya4, Koray Tasci5, Emir Celik6, Vesil Cemolun7, Yavuz Yilmaz8, Mehmet Sayarlioglu9, Yavuz Pehlivan9, Umit Kalyoncu10, Omer Karadag11, Timucin Kasifoglu12, Eren Erken13, Salih Pay14, Ayse Cefle15, Ayten Yazici16, Muhammed Cinar17, K. Tascilar18, None; E. Seyahi19, None; V. Hamuryuden20, None; H. Yazici21. None.

Background/Purpose: Thrombosis occurs in 20% of patients with Behcét’s Syndrome (BS) and leads to significant morbidity. There is no robust association between thrombosis in BS and the presence of hereditary thrombophilia or raised inflammatory markers. It remains a challenge to distinguish those at risk of thrombosis potentially requiring aggressive preventative therapy and those whose therapy can be reduced. There is a clear need to develop biomarkers for diagnosis and risk management in BS.

Results: MPs were prepared following venepuncture of 88 BS patients who fulfilled International Study Group Criteria for diagnosis, 21 of whom had a history of thrombosis, and 39 healthy controls (HC). MPs were identified using flow cytometry by gating for particles less than 1 μm in size and staining positively with Annexin V, which binds PS, giving a total MP count. Antibodies to CD14 (monocytes), TF, CD62P (platelets), CD144 (endothelial cells) and CD66b (neutrophils) were used to identify cellular markers. MPs were measured using calibrated automated thrombography, allowing analysis of the thrombotic potential of MPs.

Conclusion: MPs are found in higher numbers in BS patients than in HCs, and in TBS patients compared to NTBS patients. MPs are associated with thrombosis in Behçet’s Syndrome (BS).

Results: Two hundred eighty-one BD patients (44.1%) were of mucocutaneous type, whereas 356 patients (55.9%) had major organ involvement [Uveitis: 42.4% (n = 270), neurologic involvement: 6.9% (n = 44), gastrointestinal involvement 1.9% (n = 12)]. VBD developed in 20.6% (N = 131) patients during the follow-up. When the first vascular event developed, the mean disease duration was 3.5 (0–28) years and mean age 33.2 ± 8 years. After the first vascular event, IS treatment was given to 88.5% (n = 105) and AC treatment to 62.6% (n = 76) of the patients. Minor hemorrhage (as a complication likely related to AC treatment) was observed in 3 (13%) patients. A second vascular event developed in 35.9% (n = 47). The rate of new vascular event development was similar between the patients taking only ISs and AC + IS treatments after first vascular event (27.2% vs 29.6%, p = 0.78). Relapse rate was significantly higher in group taking only ACs (91.6%, p = 0.002). During follow-up, a third vascular event developed in 23.4% (n = 11) patients. The rate of new vascular event development was again similar between the patients taking only ISs and AC + IS treatments. There was no relationship between the total duration of AC treatment and number of vascular events. However, total number of vascular events negatively correlated with the age during the first vascular event (r = −0.215, p = 0.02).

Conclusion: In this study, we did not find any additional positive effect of AC treatment used in combination with ISs in the course of vascular involvement in patients with BD. Severe complications related to AC treatment were also not detected. Our results suggest that short-duration of IS treatment is the major problem in BD patients associated with vascular relapses during follow-up.

Methods: Thirty-three (30 M/3 F) patients with BS between March 2012 and April 2014 were studied. The mean age and the mean disease duration were 32 ± 7 and 4 ± 3 years, respectively. All patients had one or more type of large vessel disease such as: deep vein thrombosis of lower extremities (n = 31), pulmonary artery involvement (n = 14), vena cava superior (n = 1) or inferior thrombosis (n = 9) and Budd-Chiari syndrome (n = 5). FDG PET/CT studies were performed within the first 2 weeks of diagnosis in 23 patients. In the remaining 10, scans were obtained for activity assessment during the follow-up. Maximum standardized uptake values (max SUVs) and visual analyses were used to interpret the FDG PET/CT images. In addition, non-enhanced CT findings obtained during FDG PET/CT were recorded.

Results: FDG PET/CT was positive (SUV ≥ 2; equal to or greater than liver uptake) in 15 (45%) patients. These included 11 patients with pulmonary artery involvement (11/14, 79%). A monolateral involvement was observed in 3 (23%) patients. FDG uptake was observed in the lung parenchyma in the form of nodules, consolidations or cavities in 8, in the hilar region suggesting lymphadenopathy in 6 patients and in 1 patient suggesting thrombus of a pulmonary artery aneurysm. Among the 19 patients with major venous involvement, FDG uptake was observed in 4 patients (4/19, 21%) and these was in the femoro-popliteal vessels.

Conclusion: This preliminary survey showed that in BS, FDG uptake was mainly observed at the pulmonary parenchyma while pulmonary arteries did not show increased uptake in disease in peripheral and major veins. On the other hand, can only occasionally be discerned by FDG PET/CT. Further studies might be still be needed among immunosuppressive naïve patients.

Budd-Chiari Syndrome Due to Behcet’s Syndrome: Some Patients Present Without Liver Related Symptoms and Have a Better Outcome.

Emire Seyahi, Enkan Caglar, Serdal Ugrulu, Fatih Kantarcı, Vedat Hamuryudan, Abdullah Sonmez, Melike Melikoglu, Sebahatin Yurdakul and Hasan Yazici. 1Cerrahpasa Medical Faculty, University of Istanbul, Istanbul, Turkey, 2Bakirkoy Research and Training Hospital, Istanbul, Turkey, 3Istanbul University Cerrahpasa Medical Faculty, Istanbul University, Istanbul, Turkey, 4Cerrahpasa Medical Faculty of Istanbul University, Istanbul, Turkey, 5Istanbul University, Cerrahpasa Medical Faculty, Rheumatology, Istanbul, Turkey.

Background/Purpose: Behçet’s syndrome (BS) is a well recognized cause of Budd-Chiari syndrome (BCS), however, information about its clinical characteristics and outcome is limited. We have presented the outcome of 40 patients with BCS due to BS at the ACR 2013 meeting (1). In further analyses, we better understood that there were patients in whom BCS could exist without the presence of any liver related symptoms/signs. In the current study we compared demographic, clinical, radiologic and prognostic characteristics of these patients to those presented with overt liver related symptoms.

Methods: We reviewed the records of about 9000 patients with BS who were registered at the multidisciplinary Behçet’s syndrome outpatient clinic at Cerrahpasa Medical Faculty between July 1977 and October 2013. We identified 43 (40 male/3 female) patients who were diagnosed as having BCS. Their outcome was evaluated between September 2012 and October 2013.

Results: 43 (40 male/3 female) patients with BCS were identified. Thirty-three patients (77%) had presented with liver related symptoms such as ascites and abdominal swelling for a median duration of 1 month [IQR:0.5–2.5 months]. These patients were defined as Group I. On the other hand, 10 (21%) were silent for liver disease at presentation and were found to have BCS while being investigated for fever (n = 4), bilateral diffuse leg swelling (n = 4) and pulmonary symptoms like hemoptysis or dyspnea (n = 4). None had liver dysfunction related symptoms/signs. These patients were classified as Group II. All were diagnosed after 1990. Group I patients were somewhat older (mean age: 32.2 vs 28.7, p = 0.06) and had longer disease duration of BCS at the onset of BCS (median: 5.1 vs 2.7, p = 0.18) than Group II patients. The level of hepatic venous outflow obstruction in Group II patients was somewhat limited (2–3). We investigated the potential of PET/CT to evaluate the extent and activity of disease in vascular disease due to BS.
involved less frequently the combined IVC and hepatic veins (30 %) while it was more likely to involve isolated hepatic veins (30 %) or isolated IVC (40 %) when compared to Group I (76 %, 26 % and 3 %, respectively) (p = 0.05). Besides that, the anatomical distribution of vessels other than those involved in BCS, and the clinical characteristics of BS were not very different than Group I. By the end of the survey, there was only 1 death in Group II, which was not due to hepatic failure. Mortality was significantly lower among Group I patients (1/10) as compared to Group II (19/33, 58 %), (p = 0.025). By the end of the survey, only 1 (1/10) in Group I, had ascites, while in the remaining surviving patients in Group I ascites had resolved within 6 to 8 months after the first visit. A final hepatic Doppler USG indicated that, the frequency of recanalisation and collateral formation was similar between the patients in Group I and II.

Conclusion: There is subgroup of patients in whom, BCS may exist without the presence of liver related symptoms/signs and these patients have a good prognosis. These patients could pass unnoticed, unless one looks carefully for hepatic veins or intra or suprahepatic segments of the IVC. The fact that, 8 of these 10 patients were diagnosed after 2000, suggests that this would help developing effective management strategies.

Methods: 120 patients, all fulfilling the International Study Group (ISG) criteria for BD. The study enrolled 120 patients, all fulfilling the International Study Group (ISG) criteria for BD. The male/female ratio was 1.6:1, with a mean disease duration of 11.6 years. Their mean age was 42 ± 8 years (min:18, max:77), while the mean age at disease onset was 24±5 years. The principal end-point was to study any potential correlation between quality of life and disease activity. Disease activity was evaluated by means of the Behcet’s Disease Current Activity Form (BDCAF), while the Italian version of the Short-form-36 (SF-36) questionnaires were filled by consecutive BS patients attending our outpatient clinic. Socioeconomic factors, each type of organ involvement during the disease course, during the previous 4 weeks, disabilities caused by each, treatment modalities and overall disease activity were tested with regression analysis as possible determinants of quality of life. Men and women were also analyzed separately.

Results: 322 patients (M/F: 166/156, mean age: 37.9±11.1 years) were included. 157 patients had eye involvement, 72 patients had vascular involvement, 67 patients had joint involvement, 20 patients had neurologic involvement, 2 patients had gastrointestinal involvement and 93 patients had only mucocutaneous involvement without major organ involvement. Determinants of BDQoL in the whole group were BSAS, household income, work disability, perception of insufficient income, neurologic and mucocutaneous involvement. Among women they were BSAS, perception of insufficient income, neurologic and mucocutaneous involvement (R²:0.47, F: 19.75, p<0.001). Among men they were BSAS, perception of insufficient income, vascular involvement during the last 4 weeks and damage caused by neurologic involvement (R²:0.06, F: 29.70, p<0.001). SF-36 scores were well correlated with BDQoL scores (r = -0.69 for physical component and r = -0.63 for mental component).

Conclusion: In addition to overall disease activity and neurologic damage, mucocutaneous involvement in women and recent eye and vascular events in men seem to impair quality of life in BS. These findings are important for developing management strategies and outcome measures.

Reduced Heart Rate Variability in Patients with Behcêt’s Disease. Jong-Wook Lee1, Seung-Geun Lee2, Eun-Kyong Park2 and Geun-Tae Kim2.

1Division of Rheumatology, Department of Internal Medicine, Busan St. Mary's center, Busan, South Korea, 2Division of Rheumatology, Department of Internal Medicine, Pusan National University Hospital, Busan, South Korea. Division of Rheumatology, Department of Internal Medicine, Kosin University College of Medicine, Busan, South Korea.

Background/Purpose: The autonomic nervous system, including the sympathetic and parasympathetic nervous systems, has an important role in the triggering of ventricular arrhythmias and sudden cardiac death. The aim of this study was to investigate autonomic regulations by means of heart rate variability (HRV), influence of conventional cardiovascular risk factors, and relationship with the disease activity in patients with Behcet’s disease (BD).

Methods: 50 patients with BD (Age: 43.8 ± 18.6, female: 40) and 50 age-and sex-matched healthy controls were included in this study. All the participants were screened for basic cardiovascular risk factors.

BD activity was studied with Behcet’s disease current activity form (BDCAF) and acute phase indices. HRV was calculated by time domain measures, frequency domain measures and nonlinear/complexity-based measures on 24 hours recording.

Results: Patients with BD had decreased HRV in comparison to healthy controls as reflected by decrease of the standard deviation of normal R-R intervals (SDNN) (74.0 ± 20.9 vs. 83.5 ± 15.4 ms, respectively, p<0.005).

SDNN (r = -0.45, p < 0.005 and r = -0.37, p < 0.04) and HF (r = -0.42, p < 0.01 and r = -0.35, p < 0.02) were significantly correlated with BDCAF and CRP, respectively.

Conclusion: HRV was shown to be significantly decreased, compared to healthy controls, among BD patients. Patients with BD had impaired autonomic cardiac regulation which is related to the disease activity and presence of systemic inflammation and which could contribute to the increased cardiovascular risk in these patients.

Predictors of Quality of Life in Behcet’s Syndrome. Selma Bozcan1, Ersin Ozguler2, Koray Tasçilar2, Caner Saygin2, Didem Uzunaslan2 and Gulen Hatemi3.

1University of Istanbul, Cerrahpasa Medical Faculty, Rheumatology, Istanbul, Turkey, 2Cerrahpasa Medical Faculty, University of Istanbul, Istanbul, Turkey.

Background/Purpose: Quality of life is commonly impaired in patients with chronic inflammatory diseases. The disease itself as well as the drugs used may be responsible for this impairment. Behçet’s syndrome (BS) is a multisystem vasculitis with a wide variety of manifestations including oral ulcers, genital ulcers, nodular lesions, papulopustular lesions, arthritis, uveitis, venous thrombosis, arterial aneurysms, neurologic and gastrointestinal involvement. Determining the factors affecting quality of life in BS patients, would help developing effective management strategies.

Methods: Behçet Disease Quality of Life (BDQoL) and Short Form-36 (SF-36) questionnaires were filled by consecutive BS patients attending our outpatient clinic. Socioeconomic factors, each type of organ involvement during the disease course, during the previous 4 weeks, disabilities caused by each, treatment modalities and overall disease activity were tested with regression analysis as possible determinants of quality of life. Men and women were also analyzed separately.

Results: 322 patients (M/F: 166/156, mean age: 37.9±11.1 years) were included. 157 patients had eye involvement, 72 patients had vascular involvement, 67 patients had joint involvement, 20 patients had neurologic involvement, 2 patients had gastrointestinal involvement and 93 patients had only mucocutaneous involvement without major organ involvement. Determinants of BDQoL in the whole group were BSAS, household income, work disability, perception of insufficient income, neurologic and mucocutaneous involvement (R²:0.47, F: 19.75, p<0.001). Among women they were BSAS, perception of insufficient income, neurologic and mucocutaneous involvement (R²:0.40, F: 19.75, p<0.001). Among men they were work disability, BSAS, household income, perception of insufficient income, vascular involvement during the last 4 weeks and damage caused by neurologic involvement (R²:0.06, F: 29.70, p<0.001). SF-36 scores were well correlated with BDQoL scores (r = -0.69 for physical component and r = -0.63 for mental component).

Conclusion: In addition to overall disease activity and neurologic damage, mucocutaneous involvement in women and recent eye and vascular events in men seem to impair quality of life in BS. These findings are important for developing management strategies and outcome measures.

Disease Activity and Quality of Life in Behçet’s Disease: The Role of Patients Reportedoutcomes. Elena Elefante1, Rosaria Talarico2, Chiara Stagnaro2, Anna D’Acsano1, Antonio Tavoni4, Chiari Tani3, Chiara Baldini3, Marta Mosca3 and Stefano Bombardieri1.

1Rheumatology Unit, Pisa, Italy, 2Rheumatology Unit, University of Pisa, Pisa, Italy, 3University of Pisa, Pisa, Italy, 4 Immunology and Rheumatology Unit, Pisa, Italy.

Background/Purpose: Behcet’s disease (BD) is a systemic vasculitis, typically characterised by recurrent oro-genital ulcers, ocular inflammation and skin manifestations; articular, vascular, gastro-enteric and neurological involvement may also occur. Since BD has a chronic-relapsing relapsing course and it can be very severe, debilitating and potentially life-threatening, it may without any doubt affect the quality of life of the patients. Moreover, it is well known that patient’s perception of own disease represents an useful tool to help physicians to improve the understanding and management of the disease itself. The primary aim of this study was to explore the role of quality of life patients reported outcomes (PRO) in better identifying the global status of BD.

Methods: The study enrolled 120 patients, all fulfilling the International Study Group (ISG) criteria for BD. The male/female ratio was 1:6:1, with a mean disease duration of 11±6 years. Their mean age was 42±8 years (min:18, max:77), while the mean age at disease onset was 24±5 years. The principal end-point was to study any potential correlation between quality of life and disease activity. Disease activity was evaluated by means of the Behcet’s Disease Current Activity Form (BDCAF), while the Italian version of the Short-form-36 (SF-36) was used to evaluate quality of life. Disease activity was compared with the global SF-36 score and with each dimension, that includes: physical functioning, physical disability, body pain, general health, vitality, social functioning, emotional disability, mental health. The statistical analysis was performed using Student t-test, Mann-Whitney-U test, ANOVA and Pearson correlation.

Results: At time of evaluation, according BDCAF, 47 BD patients (39%) had clinically active disease (18 ocular involvement, 8 joint involvement, 4 neurological involvement, 2 gastro-enteric, 15 muco-cutanous involvement). As expected, the overall SF-36 scores were significantly lower in patients
with clinically active disease. Moreover, female BD patients had statistically significant lower scores in all SF-36 domains compared with male patients. When each domain of SF-36 was evaluated, we found that physical disability (p = 0.004), body pain (p = 0.006), general health (p = 0.001), and vitality (p = 0.001) were significantly lower in patients with disease activity. Notably, vitality (p = 0.001), physical disability (p = 0.004), social functioning (p = 0.001), emotional disability (p = 0.003) and mental health (p = 0.001) were significantly lower in patients with mucocutaneous active disease, compared with the other patients with active disease.

Conclusion: The clinicians who take care of any chronic disease would like to correctly know the current status of a patient to manage him properly. In this regard, the combination data of PRO measures and disease activity have been demonstrated to add more information compared to the evaluation of disease activity alone. These considerations suggest that the correct assessment of BD need a multi-dimensional approach that fairly includes disease activity, disease activity, disease damage and quality of life.

2756

Background/Purpose: IL-1 blocking therapy shows promise in the treatment of Behcet’s eye disease, but its effect on mucocutaneous manifestations is unknown.

Methods: 6 patients with Behcet’s disease as determined by International Study Group criteria and active oral or genital ulcers for ≥2 months were enrolled in this open label phase I/II study. 2 patients had a history of inactive uveitis (anterior, panuveitis). Study duration was 3 months with extension up to 16 months (range 4-16). All were treated with anakinra 100mg subcutaneous daily with the option to escalate dose to 200mg in partial responders after 1 month and 300mg after 6 months. Patients recorded the number and severity of oral and genital ulcers in daily diaries. The primary outcome was remission defined as no ulcers on physical exam for 2 consecutive monthly visits from months 3-6. Secondary outcomes included the number of ulcers, the number and severity of patient-reported ulcers, patient/physician global scores, and standardized disease activity scores.

Results: 2 of 6 patients achieved the primary outcome of remission from months 3-6. All but 1 had improvement in the number of oral ulcers at month 3 (primary endpoint). Mean number of oral ulcers at baseline, month 3 and month 12 were 3.3, 1.5 and 0.5 and mean number of genital ulcers were 0.8, 0 and 0. Over the entire study, patients reported ≥1 oral and ≥1 genital ulcer on 66% (66%) and 139 (14%) days, respectively. Non-statistically significant improvements were seen in secondary outcomes including physician and patient visual analog scores and scores for Behcet’s disease current activity form (BDCAF) patient index, and Behcet’s disease quality of life (BDQOL). Behcet’s syndrome activity scale (BSA) showed significant changes at 3 and 9 months. (Table). Dose escalation to 200mg occurred in all patients prior to month 3 and was further increased in 3 to 300mg after month 6. 2 patients on baseline prednisone of 40mg and 20mg were tapered to 20mg and 0mg, respectively. On anakinra 200mg vs. 100mg, patients reported fewer days with oral ulcers (65% vs 74% days, p = 0.02) and genital ulcers (10% vs 22% days, p < 0.001) and milder ulcer severity (p=0.01). Increase of anakinra to 300mg did not result in fewer ulcers or milder ulcer severity. No ocular flares occurred during the study; however, 2 ocular flares (anterior uveitis, periorbital inflammation) occurred within a month after discontinuation of anakinra in the 2 patients with prior eye disease. A diverse influx included a serious adverse event of pulmonary hypertension suspected prior to the study and frequent viral infections.

Conclusion: In this open-label pilot study, anakinra, at an optimal dose of 200mg daily, demonstrated partial efficacy in treatment of resistant oral and genital ulcers in Behcet’s disease. Organ-specific differential effects of IL-1 blockade are likely.

Background/Purpose: Behcet’s disease (BD) is a systemic large vessel vasculitis with recurrent genital and oral ulceration, uveitis, cardiovascular, joints, neurological or gut symptoms. Treatment of BD is dependent of the nature and the severity of clinical manifestations. Increased levels of TNF alpha and soluble TNF receptors have been found in the serum, plasma and in the aqueous humor of patients with BD. Although, anti-TNF alpha have proven effective in refractory uveitis, few data are available relative to its efficacy in extraocular manifestations of BD. The aim of this study is to report on the efficacy and the safety of anti-TNF alpha in BD.

Methods: We performed a retrospective multicenter study of main characteristics and outcomes of 122 patients with BD treated with anti-TNF alpha.

Results: One hundred twenty two observations were collected in 21 centers. Mean ± SD age at the anti-TNF alpha introduction was 35 ± 12 years with 47% of men. Ninety one (75%) patients received at least one immunosuppressive therapy before the use of anti-TNF alpha.

The main indications of anti-TNF alpha were uveitis (n = 80, 66%), mucocutaneous manifestations (n = 26, 21%) [oral (n = 21) and genital ulcerations (n = 13)], articular (n = 29, 24%), neurologic (n = 12, 10%), cardiovascular (n = 5, 4%), and digestive manifestations (n = 9, 7%). Infliximab was frequently used (61%), followed by adalimumab (30%), etanercept (8%) and golimumab (1%). A associated therapy included prednisolone (84%), azathio-}
hypersecretory reactions (16%). Serious adverse events were reported in 13% of patients and required treatment interruption in all cases.

**Conclusion:** These results show that TNF alpha inhibitors are highly and rapidly efficient in all BD manifestations. Although tolerance seems satisfactory, infliximab is associated with more frequent and more serious side effects.

**Predictive Factors for the Response to Infliximab Therapy in Patients with Behçet’s Disease.** Salvatore D’Angelo, Pietro Leccese, Angela Paadula, Angelo Nigo, Michele Gilio, Antonio Carriero, Carlo Palazzi and Ignazio Olivieri. Rheumatology Department of Lucania, San Carlo Hospital of Potenza and Madonna delle Grazie Hospital of Matera, Potenza, Italy.

**Background/Purpose:** To identify the clinical factors predicting a good clinical response to infliximab (IFX) therapy after 12 months in patients with Behçet’s disease (BD) refractory to conventional therapy.

**Methods:** Patients receiving IFX (5 mg/kg intravenously at weeks 0, 2, 6, and every 6–8 weeks subsequently) for BD unresponsive to conventional therapy (corticosteroids plus at least two different immunosuppressive drugs) were prospectively included. Clinical response to IFX therapy was based on the expert opinion and was graded as follows: remission, response, no response and worsening. Remission was defined as the complete disappearance of symptoms and signs of inflammation and response as at least 50% of improvement. Univariate and multivariate analyses were performed to identify factors associated with IFX good response (remission, response) at 12 months. Logistic regression analysis was performed to analyse which of the following measures at the start of treatment were associated with a good response: sex, age, disease duration, HLA-B27 status, indication for IFX treatment including uveitis, CNS involvement, severe mucocutaneous manifestations or others including arthritis, intestinal and vascular involvement; concomitant drugs including steroids (Ster), colchicine (Col), antithrombin (AHA) or cyclosporine (CSA).

**Results:** The study included 73 BD patients (47 M/26 F; mean age 33.6 ± 10.7 yrs; mean disease duration 12.3 ± 9.3 yrs; 71.2% HLA-B27 positive). Indication for IFX treatment were uveitis in 38 patients, severe mucocutaneous manifestations in 13, CNS involvement in 16, intestinal involvement in 2, arthritis in 2, vascular involvement in the remaining 2. At 12 months, 56 patients (76.7%) had a good response to IFX, 4 (5.5%) patients had stopped for adverse events, and 13 (17.8%) had stopped for primary or secondary inefficacy. In the univariate analysis concomitant use of AZA (95.6% vs 67.3%, p= 0.02) was the only factor associated with a good response. In a multivariate logistic regression analysis concomitant use of AZA was independently associated with a good therapeutic response (OR = 34.2; 95% CI 2.7–435.8; p = 0.007). None of the other variables analysed predicted response to treatment.

**Conclusion:** This study has, for the first time, shown that concomitant use of AZA at the start of IFX treatment is a factor that seems to influence the probability of achieving a good therapeutic response in patients with refractory BD. Further support from larger studies is necessary so as to optimize the management of BD patients treated with IFX.

**Anti-TNF Treatment for Refractory Vascular Involvement of Behçet’s Syndrome.** Yedet Hamuryudan1, Emire Seyahi1, Melike Elikoglu1, Serdal Ugrulu1, Gulen Haberal1, Selahattin Yurdakul2 and Hasan Yazici3. 1Cerrahpasa Medical Faculty, University of Istanbul, Istanbul, Turkey, 2Istanbul University, Cerrahpasa Medical Faculty, Rheumatology, Istanbul, Turkey.

**Background/Purpose:** The optimal management of major vascular involvement in patients with Behçet’s syndrome (BS) is still a challenge.

**Methods:** We reviewed the charts of 16 BS patients (15 with vascular involvement who had been treated with anti-TNF agents following an inadequate response to traditional immunosuppressives (cyclophosphamide or azathioprine combined with glucocorticoids).

**Results:** Ten patients had pulmonary artery involvement (PAI), 5 had major vein involvement (multiple thromboses of vena cavae, deep veins and dural sinuses) and 1 had renal artery aneurysm. PAI was in the form of pulmonary artery aneurysm (PAA) in 2 patients, pulmonary artery thrombosis (PAT) in 6 patients and the combination of PAA with PAT in 2 patients. Six patients (5 with PAI) also had intracardiac thrombi formation. All patients were using immunosuppressives at the time of initiation of anti TNF therapy (for 11 ± 7 SD months in patients with PAI and for 50 ± 51 SD months in patients with other types of vascular involvement). The initial anti TNF agent was infliximab (5mg/kg) in 15 patients and adalimumab (40 mg eow) in 1 patient who had PAI and PAT in combination. Adalimumab was used in the case of high dosages of glucocorticoids and 10 used immunosuppressives (azathioprine = 7).

At the time of survey closure (December 2013) all patients were being followed, with all but 3 being still on anti TNF therapy. None of the patients experienced an exacerbation or new development of vascular involvement under anti TNF therapy during a mean of 16.5±13.6 SD months for PAI patients and 19.5±14.9 SD months for patients with other vascular involvement. Anti TNF treatment (all infliximab) had been discontinued in 5 patients (4 with PAI). In 3 patients (2 with PAI) this was due to stable disease after a mean of 22.7±12 SD months treatment. One of these patients with PAA is on maintenance treatment with azathioprine and is symptom free 8 months after withdrawal. The second patient with PAI experienced hemoptysis due to development of a new PAT 3 years after withdrawal. He responded to re-institution of infliximab, which was switched to adalimumab because of anaemia during the second induction. The third patient with extensive venous involvement developed new venous thrombosis and secondary amyloidosis 1 year after withdrawal. His clinical status improved with re-institution of infliximab but he was also switched to adalimumab because of the development of anaphylaxis. In the 2 remaining patients with PAI infliximab was withdrawn because of serious infections (lungs tuberculosis and fungal infection). The patient developing tuberculosis is still receiving treatment for tuberculosis with no immunosuppressives and the second patient with fungal infection was subsequently prescribed interferon alpha.

**Conclusion:** Our uncontrolled experience suggests that anti TNF therapy effectively suppresses signs and symptoms of major vascular involvement in BS. Relapses can be seen after withdrawal. The development of serious infections underline the importance of close follow-up.

**Interferon Alfa-Associated Depression in Patients with Behçet’s Syndrome.** Yasin Keskin2, Emire Seyahi1, Cagri Poyraz2, Serdal Ugrulu2, Yilmaz Ozyazgan4 and Hasan Yazici4. 1Cerrahpasa Medical Faculty, University of Istanbul, Istanbul, Turkey, 2Cerrahpasa Medical Faculty, University of Istanbul, Istanbul, Turkey, 3Cerrahpasa Medical Faculty University of Istanbul, Istanbul, Turkey, 4Cerrahpasa Medical Faculty University of Istanbul, Istanbul, Turkey, 5Istanbul University, Cerrahpasa Medical Faculty, Rheumatology, Istanbul, Turkey.

**Background/Purpose:** Interferon (IFN) is an effective immune-modulatory agent in the medical management of eye disease of Behçet’s syndrome (BS). The agent is frequently associated with psychiatric adverse events, such as depressive disorders and suicide attempts are the most feared complication (1). We evaluated psychiatric status of a group of BS patients in whom IFN was used for the first time. As a control group we studied BS patients who started to use drugs other than IFN.

**Methods:** We studied BS patients who were seen between January 2012 and January 2014 at the Behçet’s syndrome outpatient clinic at Cerrahpasa Medical Faculty. Patients who have a history of psychiatric illness, who use illicit drugs/alcohol, or who have parenchymal neurological involvement due to BS were not included in the study. Patients who started to use IFN for the first time (Group 1) and those who started to use drugs other than IFN (Group 2) were studied. Beck Depression Inventory (BDI) and Hospital Anxiety and Depression Scale (HADS) were used to measure status of depression at baseline and at week 12.

**Results:** Group 1 included 17 (14 M, 3 F) while Group 2 included 21 (13 M, 8 F) patients. During 12 weeks of follow-up, in Group 1, 6 patients used corticosteroids while 3 used colchicine in addition to IFN. Drugs that were started in Group 2 were atazanavir and cyclosporine combination (n=5), infliximab (n=2), methotrexate (n=1), azathioprine alone (n=6) and colchicine (n=7). Patients who used IFN were more likely to be male, to have longer disease duration and to have eye disease. Besides that, demographic, socio-economic and clinical characteristics were similar between the Groups. A mong patients who used IFN, both BDI and HADS scores increased significantly after 3 months of follow-up. These scores did not change among patients who used other drugs (Table 2). There was no statistically significant difference among patients who answered (I have thoughts of killing
myself but I would not carry them out) to question no: 9 was more common in
the IFN group at week 12 (35 % vs 10 %, p = 0.053). These were 24 % vs 10 %,
respectively, (p = 0.24) at baseline.

Conclusion: We found that the depression scales increased among IFN
users after 12 weeks of follow-up compared to those who used other drugs.
Additionally, after 12 weeks of follow-up, the frequency of those with
suicidal ideation also increased among the IFN users. A recent survey
indicated that BS patients with major organ involvement have already
suicidal ideation also increased among the IFN users. A recent survey

Increased Risk of Parenchymal Neurological Involvement in Behçet’s Syndrome Patients with Panuveitis. Berivan Bitik1, Bema Goker2, Kubilay Sahin3, Y esim Sucullu Karadag4, Ridvan Mercan1, Abdurrahman Tufan1, Mehmet Akif Ozturk1, Fikri Ak1, Yasar Karrayan1 and Semin Haznedaroğlu1. 1Gazi University School of Medicine, Ankara, Turkey, 2Ankara Numune Education and Research Hospital, Ankara, Turkey, 3Hilt University, Corum, Turkey.

Background/Purpose: Behçet’s Syndrome (BS) is a systemic vasculitis
which may involve multiple organ systems simultaneously. Most frequently,
clinical findings in BS fit into well recognized patterns such as the association
between papulopustular skin lesions and arthritis. Neurological involvement
in BS is a serious condition which could lead to significant disability. It could
either be parenchymal or vascular. The pathogenesis of these two types of
Neuro-Behçet’s Syndrome (NBS) are suggested to be different. The purpose
of this study is to evaluate the association between the parenchymal Neuro-Behçet’s Syndrome and panuveitis.

Methods: We retrospectively reviewed the clinical records of 288 patients
with BS, who met the international classification criteria for BS, diagnosed
two major rheumatology clinics from 2000 to 2014. Patient demographics,
opthalmic examinations, clinical and radiologic patterns of neurological
involvement were recorded. Pearson’s Chi-square test was used for analysis.

Results: In this cohort of a total of 288 patients, 93 developed panuveitis
and 38 had NBS (28 men and 10 women, median age 33 (28–54)). Of the 38 patients
with neurological involvement, 28 had parenchymal and 10 had vascular disease.
Venous sinus thrombosis was the only vascular involvement in NBS patients.
Those with panuveitis were significantly more likely to have parenchymal
involvement than without panuveitis (22.6% vs 3.6%, p = 0.001) (Table 2). 21 of the 28 parenchymal NBS patients had panuveitis either
prior to or during the course of neurological involvement. Panuveitis was
significantly associated with parenchymal-NBS (OR 7.83 95% CI 3.19–19.21).

Table. The association between panuveitis and parenchymal neurological
involvement in patients with BS.

</table>

Conclusion: Among our 288 patients with BS, over one out of five
cases with panuveitis had neurological involvement during their disease course. Our findings suggest a significant association between these two major organ involves.
This association might also be defined as a recognized clinical pattern
similar to the association of papulopustular skin lesions with arthritis. BS patients
with panuveitis should be educated about possible signs and symptoms of neurological involvement which could progress quite rapidly and early initiation
of treatment is the key for success.

Atrophy of Hippocampal Region in Chronic Progressive Neuro-Behçet’s Disease. Hiroshi Kikuchi1, Kurumi Asako1, Makiko Takayama2, Yoshikata Kimura1, Akiko Okamoto1, Toshihiro Nanki2, Hajime Kono1 and Shunsei Hirohata1. 1Teikyo University School of Medicine, Tokyo, Japan, 2Teikyo University, Tokyo, Japan, 3Kitasato University School of Medicine, Sagamihara, Japan.

Background/Purpose: Central nervous system involvement in Behçet’s
disease, usually called neuro-Behçet’s disease (NB), can be classified into
acute NB (ANB) and chronic progressive NB (CPNB) based upon the differences
in clinical courses and responses to corticosteroid treatment. Previous studies demonstrated that brainstem atrophy was significantly more
frequently observed in CPNB than in ANB or non-NB. Noteworthy, in addition to truncal ataxia, neurobehavioral changes are frequently observed
in CPNB, which cannot be accounted for by brainstem atrophy. In the present
study we examined the volumes of hippocampus in order to determine the responsible lesions for neurobehavioral changes in CPNB.

Methods: A total of 26 patients were studied, including 13 patients with
CPNB (11 males and 2 females, age 51.2 ± 12.1 [mean ± SD]) and 13 non-NB
(10 males and 3 females, age 54.4 ± 11.4). All the patients satisfied the
international classification criteria for Behçet’s disease. CPNB was defined as
intractable, slowly progressive neurobehavioral changes and/or ataxia accompa-
An MRI scan is significant in CPNB than in ANB or non-NB. The severity
of gray matter loss in the hippocampal region and whole brain were investigated
by the software for Voxel-Based Specific Regional A nalysis System for Alzhei-
mer’s Disease (VSRAD) (Eisai Co., Ltd), calculating the indicators of the degrees
of hippocampal region atrophy (HAI) and those of whole-brain atrophy (WBAI).
The areas of midbrain tegmentum and pons were measured on mid-sagittal
sections of T1-weighted images of brain MRI using image analysis software
Image (NIH, U.S.).

Results: The VSRAD analysis showed that HAI was significantly
increased in CPNB (1.46 ± 0.70 [mean ± SD]) compared with in non-NB
(0.77 ± 0.40) in ANB (p = 0.0016) (Fig. 1). Although less markedly, WBAI was
significantly higher in CPNB (1.06 ± 5.00) than in non-NB (0.69 ± 1.7)
(p = 0.0240). Neither HAI nor WBAI was correlated with age. Whereas all the patients with CPNB showed brainstem atrophy, there was no significant
correlation between HAI and the rate of brainstem atrophy (Fig. 2).
Conclusion: These results indicate that hippocampus, in addition to brainstem, is a commonly affected lesion in CPNB, accounting for progressive neurobehavioral changes. The lack of correlation between brainstem atrophy and hippocampal atrophy suggest that there might be some predisposing factors determining the preference of affected lesions in CPNB.

Long-Term Outcome of Chronic Progressive Neurological Manifestations in Behcet’s Disease. Shunsei Hirohata1, Hiroshi Kikuchi2, Tetsuji Sawada3, Hiroko Nagafuchi4, M. K. Kuwana5, M. Takeno6 and Yoshiaki Ishigatsubo7. 1Kitasato Univ School of Med, Kanagawa, Japan, 2Tokyo University School of Medicine, Tokyo, Japan, 3Tokyo Medical University, Tokyo, Japan, 4St. Marianna University School of Medicine, Kanagawa, Japan, 5Ko e University School of Medicine, Tokyo, Japan, 6Yokohama City University Hospital, Yokohama, Japan, 7Yokohama City Grad Schi of Med, Yokohama, Japan.

Background/Purpose: Chronic progressive neurological manifestations in Behcet’s disease (BD) is characterized by progressive deterioration leading to disability either with or without a history of previous attacks, thus called chronic progressive neuro-Behcet’s disease (CPNBD). ATough high doses of steroids, including steroid pulse therapy, cyclophosphamide and azathioprine have been anecdotally used in the treatment of CPNBD, the prognosis of the patients treated with such drugs have been usually miserable. Notably, methotrexate has been found effective for CPNBD in prospective open trials with a small number of patients. However, its influence on the long-term outcome in a larger population remain unclear. The present study was designed to explore the effects of various treatment regimens, including methotrexate, on the prognosis of patients with CPNBD.

Methods: Thirty-seven patients, who met the international classification criteria for BD, and developed chronic progressive manifestations of NBD after 1988, were followed up until October 2013. The effects of various treatment regimens on prevention of death or severe disability of bedridden state were examined by Kaplan-Meier analysis. Cox’s proportional hazard model was used for multivariate analysis in Cox proportional hazard model.

Results: In 37 patients with CPNBD, 28 patients (75.7%) received methotrexate. Among the 28 patients with methotrexate, no patients died and only 5 patients progressed to the bedridden state. By contrast, among the 9 patients without methotrexate, 5 patients died and 3 patients progressed to the bedridden state. Thus, methotrexate significantly improved the survival of patients with CPNBD (HR 0.0507, 95% CI: 0.0077–0.334, p = 0.020 as calculated by Mantel-Cox test) (figure), but any of steroid pulse, methotrexate or cyclophosphamide did not. Methotrexate also significantly reduced the proportion of the patients who were progressed into the bedridden state or death (HR 0.0694, 95% CI: 0.0047–0.7327, p = 0.0258 as determined by multivariate analysis in Cox proportional hazard model).

Conclusion: These results indicate that methotrexate, but not high doses of steroids, azathioprine or cyclophosphamide, is effective to prevent the progression of CPNBD. Thus, it is recommended that methotrexate should be started as soon as possible the diagnosis of CPNBD is made.

S100B Astrocyte Protein May Serve As a Prognostic Factor in Reversible Cerebral Vasoconstrictive Syndromes. Juan J. Maya1, Vikram Puvenna2, Chanda Brennan3, Seby John4, Ken U Chino5, Leonhard H. Calabrese6, Damir Janigro7 and Rula Hajj-Alil8. 1Cleveland Clinic Foundation, Cleveland, OH, 2Cleveland Clinic Lerner College of Medicine, Cleveland, OH.

Background/Purpose: Reversible Cerebral Vasoconstrictive Syndromes (RCVS) are a group of disorders characterized by acute onset of recurrent thunderclap headaches with or without neurologic deficits. Radiologically, RCVS is characterized by reversible vasoconstriction; however at a molecular level the pathophysiology is poorly understood. Blood-brain barrier disruption has been linked to a variety of neurological disorders. S100B is as an astrocytic protein considered to be an important peripheral blood marker of Blood-brain barrier disruption and correlates with the presence or absence of enhancements on MRI scans. S100B serum levels have been used to study Blood-brain Barrier Disruption after traumatic brain injury, and are even being used in emergency department settings to detect traumatic brain injury. Consequently, we assessed Blood-brain Barrier Disruption in patients with RCVS by measuring the serum levels of S100B, and tested this protein for prognostic utility and risk stratification.

Methods: A total of 10 patients with RCVS from the Cleveland Clinic RCVS Biologic Repository were included in this study. A sample from each patient had been obtained during the ictal phase and samples of 3 patients were also obtained during the resolution of the vasoconstriction. S100B measurements were performed using S100B ELISA (Diasorin, Stillwater, MN). RCVS data was compared to age and gender matched historical controls, and subanalyses were performed using the data from the RCVS patients with ischemic stroke (n=5), and the RCVS patients with intracranial hemorrhages (n=4).

Results: Mean S100B level in RCVS patients during the ictal phase was statistically higher than the mean level in control group (mean = 0.3644 vs. mean = 0.072, p < 0.0001). The mean S100B level of RCVS patients with ischemic stroke (mean = 0.6588) was independently compared with the control group (mean = 0.072) and with RCVS patients with intracranial hemorrhages (mean = 0.048), the level was also statistically higher (p < 0.0001 for both comparisons). There was no statistical difference in the mean level of S100B between the control group and the group with intracranial hemorrhage (p = 0.7271). The levels of S100B in 2 out of 3 patients decreased when the initial levels were compared with the follow-up levels, in average from 0.08 to 0.05. The patient with the highest S100B level (> 3 SD above the mean) had multiple ischemic strokes and ultimately expired.

Conclusion: The elevation in S100B protein levels that was observed in RCVS patients implies that this condition can cause an alteration in the permeability of the Blood-brain Barrier. S100B levels were higher in the ischemic stroke group as compared to the hemorrhagic group and to controls. This information implies that S100B may serve as a prognostic factor in a subgroup of RCVS patients. Furthermore, RCVS patients with intracranial hemorrhage did not have a significant increase in S100B levels, which is different from what other authors have observed in non RCVS intracranial hemorrhages. Further studies with larger number of subjects are needed in order to validate and further explore this data.

Disclosure: J. J. Maya, None; V. Puvenna, None; C. Brennan, None; S. John, None; K. U. Chino, None; L. H. Calabrese, None; D. Janigro, Markers of Blood-brain Barrier Disruption and Methods of Using Same US 7,144,708; 9, Peripheral Markers of Blood Brain Barrier Permeability US 6,884,591 B2; 9, R. Hajj-Alil, None.

Background/Purpose: The pathophysiology and molecular mechanisms of Reversible Cerebral Vasocostriction Syndrome (RCVS) are unknown. Objective of the study was to identify putative biomarker proteins for RCVS.

Methods: Patients were recruited from our institution’s prospective RCVS registry. Plasma samples were collected from 6 patients with RCVS during the acute cerebral vasocostrictive phase. 2 patients at 6-month follow-up after resolution of vasocostriction, and 4 patients with CNS vasculitis.

Results: Plasma samples were immune-depleted for the most abundant plasma proteins, precipitated, and then digested overnight with trypsin and analyzed by liquid chromatography tandem mass spectrometry (LC-MS/MS). These LC-MS/MS experiments were carried out on a high resolution Orbitrap-Elite FT-MS system that allows the relative quantity of the proteins in these samples to be determined by a label free quantitative method. The quantitation is performed by searching the data with the programs Mascot and Sequest. These search results were then uploaded into the program Scaffold. The quantification was performed by comparing the normalized spectral counts (SC) for the samples. The data was filtered based on several parameters including two matching peptides, a FDR of 1%, a protein threshold of 95%, and identified in at least 3 of the samples. The relative quantity of these proteins was determined by using the spectral counting method that has been described previously. In order for a protein to be considered as a putative biomarker, the relative abundance needs to be at least two fold different with the T-test derived p-value less than 0.05.

Conclusion: This is a preliminary study looking at proteomic analysis of RCVS plasma samples. Results of this study show proteins that might be potential biomarkers for RCVS and which could help differentiate RCVS from other CNS vasculitis. Further studies with larger number of patients are needed to assess reproducibility. The function and the pathways of these differentially expressed proteins should be further explored.

Table 1: List of differentially expressed proteins identified in LC-MS/MS analysis comparing i) Baseline vs follow-up RCVS and ii) Baseline RCVS vs CNS vasculitis

2767 Core Outcome Domains and Potential Measurement Instruments in polymyalgia Rheumatica (PMR) Using Omeract Filter 2.0. Sarah Mackie1, Toby Hellwell2, Rodney Hughes2, E Brouwer4, Colin T. Pease5, Christian Mollen6, Marten Boers7 and John R. Kirwan8. 1University of Leeds, Leeds, United Kingdom, 2Keele University, Staffordshire, United Kingdom, 3St Peters Hospital, Chertsey Surrey, United Kingdom, 4University Medical Center Groningen, Groningen, Netherlands, 5Leeds Teaching Hospitais NHS Trust, Leeds, United Kingdom, 6Keele University, Keele, United Kingdom, 7VU University Medical Center, Amsterdam, Netherlands, 8Bristol Royal Infirmary, Bristol, United Kingdom.

Background/Purpose: The OMERACT PMR specialist interest group was established to develop a core outcome measurement set for PMR using the methods of OMERACT filter 2.0. This work builds on previous work undertaken to identify potential domains, which were presented at OMERACT 11.

Methods: A three-round Delphi survey was undertaken to identify domains of importance (Figure1). Additionally, meetings of patient and clinician participants were convened in order to scrutinise and finalise the candidate core domain set. A review of the PMR literature was undertaken to identify outcome measures and instruments used in previous PMR research. The candidate domains and identified instruments were presented and discussed at OMERACT 12.

2766 Mycophenolate Mofetil in the Treatment of Primary Central Nervous System Vasculitis. Carlo Salvareni1, Robert D. Brown Jr.2, Teresa J. H. Christiansen1, John Huston III1, Francesco M uratore3, Caterina Giannini4, and Gene G. Hunder5. 1University of S Maria Nuova, Reggio Emilia, Italy, 2Mayo Clinic, Rochester, MN.

Background/Purpose: The optimal management of primary central nervous system vasculitis (PCNSV) remains unclear. Cyclophosphamide (CYC) in combination with glucocorticoids (GCs) or GCs alone are the most commonly used therapies. It is not proven if other immunosuppressants, used in other vasculitides, such as azathioprine (AZA), methotrexate (MTX) and mycophenolate mofetil (MMF), that are less toxic than CYC, can be used as induction and/or maintenance therapies. The aim of the study was to determine the efficacy and safety of MMF in PCNSV.

Methods: The study cohort consisted of 163 consecutive patients with PCNSV seen at Mayo Clinic (Rochester, MN) from 1983 to 2011. The diagnosis of PCNSV was based on findings of brain or spinal cord biopsy, cerebral angiography, or both. To assess treatment response, we used the physician’s global opinion about the response to therapy. The degree of disability was defined using the modified Rankin scale. Outcomes, relapses, treatment response and ability to discontinue treatment at last follow-up were compared between patients treated with MMF and those receiving other therapies.

Results: 159/163 patients were treated at the time of diagnosis: 68 received GCs alone, 72 GCs and CYC, 2 CYC alone, 10 MMF and GCs, 6 AZA and GCs, and 1 rituximab and GCs. 6 more patients were treated with MMF after obtaining remission with CYC. In total, 16 patients were treated with MMF: 7 males and 9 females with a median age of 45.5 years (range: 20–72 years). Cerebral biopsy was performed in 10 and was positive in 9 (3 associated cerebral amyloid angiopathy). Clinical manifestations at presentation were: headache (9 patients), altered cognition (9 patients), persistent neurologic deficit or stroke (8 patients), seizures (6 patients) and 1 had intracranial hemorrhage. Cerebral MRI showed infarctions in 10 patients (bilateral in 7) and prominent leptomeningeal enhancement in 4 patients. CSF abnormalities were observed in 14/16 patients. The median duration of follow-up was 34 months (range: 10–78 months). Cerebral angiography was positive in 7/11 patients and large vessel involvement was observed in 4. The median dose of MMF was 2 grams (range: 0.5–3 grams) and the median therapy duration 14.9 months (range: 1–31.6 months). Rankin disability scores at diagnosis were similar between patients treated with MMF and those receiving other therapies (Rankin score, 0–3: 68.7% versus 69.9%; Rankin score, 4–6: 31.3% versus 30.1%; p = 1.000). A significantly lower proportion of patients treated with MMF had severe disability at last follow-up compared to those receiving other therapies (Rankin score, 4–6: 0 versus 25.1%, p = 0.023). No statistically significant differences were observed in patients treated with MMF compared to those receiving other therapies regarding relapses [7/16 (43.7%) versus 37/142 (25.9%), p = 0.146], ability to discontinue therapy at last follow-up [4/16 (25%) versus 36/142 (25.3%), p = 1.000], and treatment response [15/15 versus 111/142 (78.1%), p = 0.075]. Only 1 patient suspended MMF for a severe adverse event (leukopenia).

Conclusion: In this retrospective study of a small number of PCNSV patients, MMF was an effective and safe therapy.

N: Number of studies; VAS: Visual analogue scale; CRP: C-reactive protein; ESR: Erythrocyte sedimentation rate; SAE: Serious adverse event; AE: Adverse event; SF36: Short-Form-36; ADL: Activities of daily living; HAQ: Health Assessment Questionnaire Disability Index

No study reported any patient involvement in the development of the outcome measures used. The candidate core domain set emerging after discussion at the OMERACT 12 PMR special interest group is shown in figure 2. Two studies undertook instrument validation and demonstrated poor test-retest reliability for fatigue VAS, morning stiffness duration, and SF36 mental component score and that the HAQ performed well for PMR.

**Conclusion**: The over glucocorticoid (GC) adverse effects (AEs) warrants their inclusion in the core set. No accepted measurement instrument for GC AEs was identified. GC AEs were not routinely reported in the studies. The literature review identified 28 studies for full review. Results: The mean relative changes of the CRP/ESR and PROs from baseline to 4th and 16th week were not statistically different between Pd and MR-Pd (p > 0.05), confirming their same efficacy at the same dosage. We noticed the highest after 4 weeks CRP, fatigue, stiffness duration and HAQ assessment showed a better response in the group treated with modified release CS (CRP SRM 1.03–0.71; fatiguer SRM 1.25–0.80; stiffness duration 1.40–0.00, HAQ SRM 1.74–1.10 for modified and immediate release Prednisone respectively). However at week 16 there were no significantly differences between CRP and HAQ (SRM 0.56 - 0.67 and 1.83 – 1.02 respectively), whereas fatigue and stiffness duration improved in patients treated with Pd (SRM 1.12 – 0.07 and 0.72 – 0.10). Otherwise impact on stiffness intensity was constantly better in patients treated with Pd (after 4 and 16 weeks respectively; SRM 1.70–1.15 and 4.19–1.16).

**Disclosure**: M. Betelli, None; G. Erba, None; M. Ricci, None; C. Valena, None; E. Allevi, None; M. Riva, None; G. Grosso, None; S. Barbarossa, None; F. Bonomi, None; M. R. Pozzi, None.

**Results**: The mean relative changes of the CRP/ESR and PROs from baseline to 4th and 16th week were not statistically different between Pd and MR-Pd (p > 0.05), confirming their same efficacy at the same dosage. We noticed the highest after 4 weeks CRP, fatigue, stiffness duration and HAQ assessment showed a better response in the group treated with modified release CS (CRP SRM 1.03–0.71; fatigue SRM 1.25–0.80; stiffness duration 1.40–0.00, HAQ SRM 1.74–1.10 for modified and immediate release Prednisone respectively). Otherwise impact on stiffness intensity was constantly better in patients treated with Pd (after 4 and 16 weeks respectively; SRM 1.70–1.15 and 4.19–1.16).

**Conclusion**: Modified-Release Prednisone and Prednisone showed the same overall efficacy on Patient Reported Outcomes and acute phase reactants in patients with PMR, but with different timings and impacts on various disease aspects.

**Disclosure**: M. Betelli, None; G. Erba, None; M. Ricci, None; C. Valena, None; E. Allevi, None; M. Riva, None; G. Grosso, None; S. Barbarossa, None; F. Bonomi, None; M. R. Pozzi, None.

**Background/Method**: Polymyalgia rheumatica (PMR) is a chronic inflammatory disorder of the elderly, characterised by morning stiffness, pain and aching in the hip and shoulder girdles and acute phase reactants increase. The response to low-dose prednisone (Pd) is marked and fast on both Patient Reported Outcomes (PROs) and acute phase reactants, but most patients require a treatment course of 1-3 years. A new modified-release delivery system Prednisone adapts the release of the administered glucocorticoid to the circadian rhythms and proved to be useful for morning stiffness, fatigue and disease activity control in Rheumatoid Arthritis. We compared Prednisone (Pd) to modified release Prednisone (MR-Pd) on PROs and acute phase reactants in Polymyalgia Rheumatica.

**Methods**: We studied 15 patients (5 men, mean age 70 years, SD 8.25) with newly diagnosed PMR and previously untreated. They received the same tapering dose of prednisone starting from 15 mg: 8 patients received a MR-Pd tablet, and 7 a Pd tablet. We observed no drop-outs but only ten patients have completed the 16-week assessment period by now (3 men, mean age 72 years, SD 5.48). CRP/ESR, VAS for stiffness duration/intensity and fatigue and HAQ-DI (PROs) were obtained at baseline and at week 4 and 16. We used Standardized Response Means (SRM), a measure of responsiveness, to evaluate acute phase response and clinical parameters improvement at week 4 and 16.

**Disclosure**: M. Betelli, None; G. Erba, None; M. Ricci, None; C. Valena, None; E. Allevi, None; M. Riva, None; G. Grosso, None; S. Barbarossa, None; F. Bonomi, None; M. R. Pozzi, None.

Koc University Faculty of Medicine, Istanbul, Turkey.

**Background/Method**: To evaluate the diagnostic and discriminative ability of the new 2012 European League Against Rheumatism (EULAR)/ American College of Rheumatology (ACR) polymyalgia rheumatica (PMR) classification criteria compared to previous four diagnostic/classification criteria for PMR in a multicenter prospective study.

**Methods**: One-hundred and five patients older than 50 years of age, presenting with new onset (symptom duration = 12 weeks) bilateral shoulder pain with elevated acute phase reactants were enrolled from 9 rheumatology clinics in Turkey. Patients were prospectively followed and the diagnosis of PMR was established when the diagnosis was maintained without an
Studies evaluating ultrasound (US) as a diagnostic tool in GCA have reported a high sensitivity and specificity. The aim of this study was to investigate the association between disease’s relapse and co-existing “silence” LVV in patients with PMR.

**Methods:** Patients with PMR who relapsed under corticosteroid (CS) tapering in Esbjerg Hospital, Denmark in the period of April 2013 to June 2014 have been prospectively included. In patients with PMR who relapsed under corticosteroid (CS) tapering, US examination of temporal (AT), axillary (AA), subclavian (AS) and carotid (AC) arteries was performed. US images were recorded and evaluated by an ultrasonographer experienced on vascular ultrasound (AD), who was blinded to patients’ clinical and laboratory data.

US was considered positive when a homogeneous hypoechoic thickness >1 mm in AC and AS and >1 mm in AA, in transverse and longitudinal view was observed. For the AT, the typical sign of halo (arterial wall swelling in transverse and longitudinal view) was considered as vasculitis. Relapse was defined as the reappearance of PMR clinical symptoms in addition to elevated ESR or CRP (ESR > 40 mm/h, CRP >10mg/l) or persistent increased CRP/ESR without any other explanation. All patients with positive US findings underwent TAB.

**Results:** On a period of 14 months, 17 patients had been evaluated. All patients fulfilled the Bird’s classifications criteria for PMR and all the patients responded appropriately to CS treatment at baseline. None of the patients had GCA-related clinical symptoms either on baseline or during the relapse. No significant differences were observed between the two groups of patients (PMR + LVV and PMR - LVV) in age, diseases duration, initial CRP/ESR levels and initial CS dose (prednisolon 15-25mg).

Seven out of 17 (41%) patients had ultrasonographic sign of vasculitis. All patients had affection of the AA (6 of them bilateral), 3 of the AS, 1 of the AT none of the AC. The patient with the positive US of the AT was the only who had a positive TAB.

**Conclusion:** In our study, the relationship between PMR relapse and concomitant “silence” LVV has been evaluated. More than one-third of PMR patients who relapsed had a co-existing LVV. Thus, we recommend the use of vascular US in all patients with PMR suffering a relapse to investigate the possible co-existence of LVV.

**PET-CT Imaging and Association of Ferritin Autoantibodies in Polymyalgia Rheumatica**

Niklas Thomas Baerlecken*, Torsten Witte*, Marco Amedeo Cimmino² and Dario Camellino³. ¹MD, Hannover, Germany, ²MD, Hanover, Germany, ³Università di Genova, Genova, Italy, ⁴Clinica Reumatologica, Genova, Italy.

**Background/Purpose:** Previously we described antibodies against ferritin heavy chain peptide (anti-FHCP) in sera of patients with giant cell arteritis (GCA) and/or polymyalgia rheumatic (PMR) before glucocorticoid treatment was initiated. In that study, it remained unclear however, whether the PMR patients may have suffered from additional undiagnosed GCA. Therefore, we now measured antibodies against FHCP in PMR patients in whom GCA had been excluded by FDG-PET scan.

**Methods:** Sera of 63 patients were studied that presented initially with symptoms of PMR. A PET-CT had been performed in all patients and revealed large vessel vasculitis in 27 of these patients (GCA/PMR), whereas 36 had no signs of vasculitis (PMR). In a single-blinded study, we measured anti-FHCP in these patients and in a control group of patients with rheumatic diseases (RD, n=26), malignant diseases (MD, n=15) and infectious febrile diseases (IFD, n=22).

In the ELISA 3 peptides of the ferritin heavy chain were used as antigens: A19-45 (A19RNQINELASYVLLSMYFYFDFR), A79-104 (GRIFQDIKKPCDDWESGLNACMA) and A105-143 (LHKEKVNQOSLHLKLDTKNDHPHLFCTHYNEVQK).

**Results:** The frequency of antibodies against A19-45 were 38/63 (60%) in all PMR patients and 14/63 (22%) in controls (p<0.0001), of antibodies against A79-104 30/63 (48%) in all PMR patients and 9/63 (14%) in controls (p<0.0001) and of antibodies against A105-143 38/63 (60%) in PMR and 12/63 (19%) in controls (p<0.0001). There were no differences within the controls considering all antibodies.

Comparing the patients with and without vascular involvement in PET-CT, the frequencies of antibodies against A19-45 (18/27 (67%) and 20/36 (56%), (p=0.53)), against A79-104 (14/27 (52%) and 16/36 (44%) (p=0.74) and against A105-143 (19/27 (70%) and 19/36 (53%) (p=0.25) were not different.

**Conclusion:** This single-blinded study confirms the frequency of anti-FHCP in a different cohort. Anti-FHCP are associated with both GCA/PMR and PMR only.

**Disclosure:** N. T. Baerlecken, None. T. Witte, None. M. A. Cimmino, None. D. Camellino, None.

**Polyvaskyulite Rheumatika: Relapse and ‘Silence’ Large Vessel Vasculitis: Is There Any Association?**

Stavros Chrysidi, Philip Rask Lange-Hansen, and Amedeo Cimmino. Department of Rheumatology, Hospital of Southwest Denmark, Esbjerg, Denmark, Hospital of Southern Norway Trust, Kristiansand, Norway.

**Background/Purpose:** Large Vessel Vasculitis (LVV) can present with heterogeneous clinical manifestations, which range from general symptoms (fever, loss of weight) to the classic symptoms of Giant Cells Arteritis (GCA) (headache, jaw claudication, visual manifestations). Around 40% of GCA patients have concomitant Polyvaskyulite Rheumatika (PMR) and up to 40% of PMR patients have a positive biopsy of the temporal artery (TAB).

Studies evaluating ultrasound (US) as a diagnostic tool in GCA have reported a high sensitivity and specificity. We now measured antibodies against the heavy chain peptide of ferritin (anti-FHCP) in sera of patients with GCA/PMR, whereas 36 had no signs of vasculitis (PMR). In a single-blinded study, we measured anti-FHCP in these patients and in a control group of patients with rheumatic diseases (RD, n=26), malignant diseases (MD, n=15) and infectious febrile diseases (IFD, n=22).

In the ELISA 3 peptides of the ferritin heavy chain were used as antigens: A19-45 (A19RNQINELASYVLLSMYFYFDFR), A79-104 (GRIFQDIKKPCDDWESGLNACMA) and A105-143 (LHKEKVNQOSLHLKLDTKNDHPHLFCTHYNEVQK).

**Results:** The frequency of antibodies against A19-45 were 38/63 (60%) in all PMR patients and 14/63 (22%) in controls (p<0.0001), of antibodies against A79-104 30/63 (48%) in all PMR patients and 9/63 (14%) in controls (p<0.0001) and of antibodies against A105-143 38/63 (60%) in PMR and 12/63 (19%) in controls (p<0.0001). There were no differences within the controls considering all antibodies.

Comparing the patients with and without vascular involvement in PET-CT, the frequencies of antibodies against A19-45 (18/27 (67%) and 20/36 (56%), (p=0.53)), against A79-104 (14/27 (52%) and 16/36 (44%) (p=0.74) and against A105-143 (19/27 (70%) and 19/36 (53%) (p=0.25) were not different.

**Conclusion:** This single-blinded study confirms the frequency of anti-FHCP in a different cohort. Anti-FHCP are associated with both GCA/PMR and PMR only.

The Use of Imaging in the Diagnosis of Polymyalgia Rheumatica: Systematic Literature Review and Meta-Analysis. Sarah Mackie,1 Gouri Koduri,1,2 Catherine L. Hill,1 Andrew Hutchings,1 Richard J. Wakefield,1 Bhashkar Dasgupta2 and Jeremy Wyatt.1 1University of Leeds, Leeds, United Kingdom, 2Leeds Musculoskeletal Biomedical Research Unit and Leeds Institute of Rheumatism and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom.

Background/Purpose: ACR/EULAR provisional classification criteria for polymyalgia rheumatica (PMR) incorporate musculoskeletal ultrasound of shoulder and hip (bursitis and synovitis given equal weight). Our objective was to systematically review diagnostic accuracy of imaging features of PMR: the reference standard was rheumatologist diagnosis.

Methods: Data sources were MEDLINE, EMBASE and PubMed searches; hand-searching, and experts in the field. Two authors independently reviewed search outputs and discussed disagreements. 1746 citations yielded 23 eligible studies. Data were extracted by two authors independently. Methodological quality was assessed by 3 authors using QUADAS-2. Hierarchical summary receiver operating curve (HSROC) models were constructed where appropriate, and positive/negative likelihood ratios (LR +/ LR-) calculated.

Results: 23 studies with data from 2328 patients were evaluated: musculoskeletal ultrasound (9 studies), vascular ultrasound (6), magnetic resonance imaging (MRI) (6), and positron emission tomography (PET) (2). One further article (musculoskeletal ultrasound) was published during the preparation of this review. Internal and external validity varied, as did the clinical spectrum. All but one of the studies had a diagnostic case-control design. The most useful imaging features were subacromial-subdeltoid bursitis (SAB) on one or both sides (4 ultrasound studies: LR + 2.5 (1.6 to 3.8); LR - 0.30 (0.11 to 0.81), bilateral SAB (4 ultrasound studies: LR + 2.2 (1.2 to 32); LR - 0.38 (0.15 to 0.97), and presence of trochanteric bursitis (2 ultrasound, 1 MRI and 1 PET study: LR + 5.4 (3.3 to 8.8), LR - 0.076 (0.002 to 0.28). Hip or shoulder synovitis LRs were closer to the non-informative ratio of 1.0. Interspinous bursitis (LR + 4.5 (1.5 to 13), LR - 0.26 (0.093 to 0.73)) and ischiogluteal bursitis (LR + 3.6 (1.5 to 8.8), LR - 0.19 (0.05 to 0.69)) were detected by PET scans rather than ultrasound.

Conclusion: Based on current evidence, the most useful imaging features for the diagnosis of PMR appear to be SAB, bilateral SAB and trochanteric bursitis, rather than shoulder or hip synovitis.

Whole-Body MRI Reveals Characteristic Extracapsular Pattern of Inflammation in Polymyalgia Rheumatica. Sarah Mackie,1 Gouri Koduri,1,2 Catherine L. Hill,1 Andrew Hutchings,1 Richard J. Wakefield,1 Bhashkar Dasgupta2 and Jeremy Wyatt.1 1University of Leeds, Leeds, United Kingdom, 2Leeds Musculoskeletal Biomedical Research Unit and Leeds Institute of Rheumatism and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom.

Background/Purpose: Polymyalgia rheumatica (PMR) is a disease of widespread musculoskeletal inflammation characterized by pain and stiffness in shoulder and hip girdles. Here we report the first use of whole-body MRI to study the clinical spectrum of PMR in the rheumatology clinic. We hypothesized that PMR is characterized by an extracapsular pattern of inflammation.

Methods: 38 participants underwent whole-body MRI: 22 consecutive cases of clinically-diagnosed, active PMR identified by two rheumatologists with a special interest in PMR and followed up for a mean of 21 months; and 16 patients (controls) selected from a larger inflammatory arthritis (RA) cohort. 4 of the PMR patients did not have gadolinium enhancement, due to contra-indications. A nonmised gadolinium-enhanced MRI scans were consensus scored in axial view using semi-quantitative grading, and the features best discriminating PMR from RA were identified. Patients were treated after the MRI with 15mg prednisolone and then asked at follow-up whether they no felt back to normal.

Results: A characteristic pattern suggesting PMR was classified as "PMR pattern" by the blinded scorers; this could be identified both on the gadolinium-enhanced and non-enhanced scans. The features best discriminating PMR from RA were inflammation in the following sites: extending up around the rim of the acetabulum ("peri-acetabular"); around the ischial tuberosity; within the hip joint; around the greater trochanter; and around the symphysis pubis (Figure). Of all the MRIs performed in patients with a clinical diagnosis of PMR, "PMR pattern" was significantly associated with patient-defined glucocorticoid responsiveness (p=0.01).

Conclusion: A characteristic, extracapsular pattern of inflammation in PMR can be identified, and defines a subgroup of the clinical spectrum of PMR with excellent patient-reported glucocorticoid responsiveness. MRI is particularly useful in assessing inflammation of structures around the pelvis.

Why Leg Ulcers Do Not Heal? a Prospective Study Showing High Proportion of Small Vessel Vasculitis. Vinod Ravindran, Sunil Rajendra and Ranjish Vijayan. 1National Hospital, Kozhikode, Kerala, India, 2PVS Hospital, Kozhikode, India.

Background/Purpose: Non healing cutaneous ulcers of lower limbs can have several different aetiologies [1]. It is likely that the patients with such ulcers would be treated with empirical therapies and may also undergo (unnecessary) venous procedures. Small vessel vasculitides (leucocytoclastic or non leucocytoclastic) are one of the important causes of non healing cutaneous leg ulcers [2]. The primary objective of this prospective study was to ascertain the cause of non healing cutaneous ulcers of the lower limbs.

Methods: Between May 2010 and April 2013 (3years) consecutive adult patients (age 18 to 75 years) who had one or more persistent leg ulcers (with or without a history of recurrent ulcerations in legs) for more than 2 years presenting to us were prospectively enrolled. Relevant details were extracted using a predefined proforma and included: demographic details, drug history, comorbidities, clinical features, investigations including ANCA, complement levels, cryoglobulins, HIV and Hepatitis viral serology etc. and venous and arterial Dopplers, microscopy and culture of the ulcer swab in instances of infected looking ulcers. Previous biopsies were reviewed and fresh biopsies were obtained from the ulcer edges and also from the nonulcerated sites where suitable skin lesions were also present. In cases of ulcers deemed to be a manifestation of a primary systemic vasculitis based on the EMEA classification, BVAS was used to assess disease activity.

Results: A total of 51 patients were assessed. Mean age was 53 ± 10.3 years and 39 (76%) were male. Eight (16%) patients were diabetic. History of some type of venous surgery was present in 30 (59%) and 9 had such procedures more than once. Biopsy confirmed small vessel vasculitis of various types in a majority (76%) of patients (table 1). Drug induced cutaneous vasculitis was not present in this cohort.
Drug-Associated Cutaneous Vasculitis: Study of 239 Patients from a Single Referral Center. Montserrat Santos-Gómez1, Francisco Ortiz Sanjuan1, Ricardo Blanco1, Jose L. Hernández2, Vanesa Calvo-Rio1, Javier Loricera1, Carmen Gonzalez-Vela2, Trinitario Pina Murcia1, Hector Blanco1, J. L. Loricera1, Carmen Gonzalez-Vela2, Victor Martinez-Taboada1, Javier Rueda-Gotor1, Leyre Riancho-Zarrabeitia3 and Miguel A. Gonzalez-Gay1. 1Hospital Universitario Marqués de Valdecilla. IDIVAL. Santander. Spain, 2Sanidad, Santander, Spain, 3Epidemiology, Genetics and Atherosclerosis Research Group on Systemic Inflammatory Diseases, Rheumatology Division, IDIVAL, Santander, Spain.

Background/Purpose: The 2012 International Chapel Hill Consensus Conference on the Nomenclature of Vasculitides defined drug-associated immune complex vasculitis as a distinct entity included within the category of vasculitis associated with probable etiology. In the present study we assessed the clinical spectrum of patients with drug-associated cutaneous vasculitis (DACV).

Methods: Case records of patients with DACV attending to a tertiary referral hospital over a 36-year period were reviewed. A diagnosis of DACV was considered if the drug was taken within a week before the onset of the disease.

Results: 239 (30.9%) patients (133 men and 106 women with a mean age of 36 years) from a series of 773 unselected cutaneous vasculitis were diagnosed with DACV. Antibiotics (n = 149; 62.3%) -mainly β-lactams-, and non-steroidal anti-inflammatory drugs (NSAIDs) (n = 24; 10%) were the most common drugs. Besides skin lesions (100%), the most common clinical features were joint (51%) and gastrointestinal (31%) manifestations, nephropathy (34.7%), and fever (23.8%). The most remarkable laboratory data were increased erythrocyte sedimentation rate (40.2%), presence of serum cryoglobulins (26%), leukocytosis (24.7%), positive antinuclear antibodies (21.1%), anemia (18.8%), and positive rheumatoid factor (17.5%). Despite drug discontinuation and bed rest, 108 patients (45.2%) required medical treatment, mainly corticosteroids (n = 71) or immunosuppressive drugs (n = 7). After a median follow-up of 5 months, relapses occurred in 10.4% of patients, and persistent microhematuria or renal insufficiency in 3.3% and 2.9%, respectively.

Conclusion: DACV is generally associated with antibiotics and NSAIDs. In most cases it has favorable prognosis, although a small percentage of patients may develop residual renal damage.

Clinical-Biological Spectrum and Therapeutic Management of Hypocomplementemic Urticarial Vasculitis: Data from a French Nationwide Study on 57 Patients. Marie Jachiet1, Alain Le Quercuum1, Alain Deroux2, Pascal Godmer3, Mikael Ebb3, Leonardo A. Studer4, Beatrice Chevalier5, Nicolas Dupin6, Selim Aractingi1, Luc Guillevin for the French Vasculitis Study Group5, Luc Mouthon7 and Benjamin Terrier1. 1Cochin Hospital, Paris, France; 2Division of Internal Medicine, Hôpital Saint-Eloi, Centre Hospitalier Universitaire de Montpellier, Montpellier, France, 3CHU Grenoble, Grenoble, France; 4Department of Internal Medicine, Centre Hospitalier Bretagne Atlantique de Vannes, Vannes, France; 5CHU, Mar-selle, France, 6CHU, Toulouse, France, 7Saint Louis, Paris, France. 8Service de Dermatologie, Hôpital Cochin, AP-HP, Paris, France. 9National Referral Center for Rare Systemic Autoimmune Diseases, Hôpital Cochin, AP-HP, Université Paris Descartes, Paris, Paris, France.

Background/Purpose: Hypocomplementemic urticarial vasculitis (HUV), an uncommon vasculitis of unknown etiology, is rarely reported. It is also called anti-C1q vasculitis in the 2012 revised International Chapel Hill Consensus Conference Nomenclature for Vasculitides. Information on its presentation and therapeutic management is scarce.

Methods: To analyze the clinical spectrum and therapeutic management of HUV patients, we conducted a French nationwide retrospective and transdisciplinary study on behalf of the FVSG that included 57 patients with chronic urticaria, histological leukocytoclastic vasculitis and hypocomplementemia as inclusion criteria.

Results: The 57 identified patients had a median age at diagnosis of 45 (range 15–83) years, and 42 (74%) were women (sex ratio 2.8). HUV was
isolated in 43 (75%) patients, while the remaining 14 (25%) were associated with systemic lupus erythematosus (n=10), primary Sjögren’s syndrome (n=2), systemic sclerosis and lung cancer (n=1 each). Urticarial lesions were typically erythematous papules, more pruritic than painful, associated with angioedema (51%), purpura (35%) and/or livedo reticularis (14%). Excruciating manifestations included constitutional symptoms (56%), musculoskeletal (82%), ocular (56%), pulmonary (19%), gastrointestinal (18%) and/or kidney involvement (14%). HUV patients typically had low C1q-complement and normal C1-inhibitor levels with 35% of them also having anti-C1q antibodies. Patients with anti-C1q antibodies had more frequent systemic HUV, angioedema, livedo reticularis, ocular, musculoskeletal and/or kidney involvement(s), and less frequent pulmonary and/or gastrointestinal involvement(s). Hydroxychloroquine (HCQ) or colchicine seemed to be as effective as corticosteroids as first-line therapy. For patients with relapsing and/or refractory HUV, higher cutaneous and immunological response rates were obtained with immunosuppressants, particularly azathioprine (AZA), myophenolate mofetil (MMF), cyclophosphamide or rituximab (RTX)-based regimens, with the latter apparently more effective. Finally, cutaneous and immunological responses were strongly associated.

Conclusion: HUV is an uncommon systemic and relapsing vasculitis with various manifestations, mainly musculoskeletal and ocular. Half of the patients have anti-C1q antibodies. HCQ and colchicine should be the first-line therapy, whereas corticosteroids alone or combined with an immunosuppressant, preferably AZA, M.M.F. or RTX, could be alternative therapeutic options for relapsing or refractory disease.

Background/Purpose: Non-systemic vasculitic neuropathy (NSVN) is a small-to-medium-sized vessel vasculitis limited to the peripheral nervous system. It can be considered a single-organ vasculitis, as recently defined in the revised International Chapel Hill Consensus Conference Nomenclature of Vasculitides in 2012. NSVN is probably an underdiagnosed entity that has rarely been reported. This descriptive study was undertaken to ascertain its presentation, therapeutic management and outcome.

Methods: We retrospectively analyzed 18 patients with NSVN fulfilling criteria proposed by Collins in 2010, including: 1) peripheral neuropathy, 2) vasculitis histologically proven on neuromuscular biopsy, 3) possible constitutional symptoms, and 4) absence of systemic manifestations or laboratory markers suggestive of systemic vasculitis or connective tissue disease.

Results: Ten women and 8 men, median age 51 (range 27–83) years, were included. Neurological manifestations were characterized by acute onset (76%), mononeuritis multiplex (88%), polyneuropathy (12%), sensory impairment (100%) and motor impairment (88%). Neurological manifestations were painful (86%) and asymmetrical (78%). Nerve trunks involved were external popliteal (94%), internal popliteal (44%), ulnar (33%), radial (17%) and median (11%). General symptoms included asthenia and weight loss (>10% (22%) each), arthralgias (12%) and fever (6%). Only 2 patients had elevated inflammatory parameters. Neuromuscular biopsy showed, in muscle or nerve, medium-sized-vascular vasculitis (56%) or small-sized-vascular vasculitis (44%), with fibrinoid necrosis (88%). Corticosteroids were prescribed to 94%, and their NSVN regressed significantly (65%), stabilized (2%) or progressed (24%). Cyclophosphamide was added to corticosteroids for refractory patients. Relapsing patients received methotrexate or azathioprine, with 3/4 patients showing improvement. After median follow-up of 47 months, neurological sequelae were noted in 83%, including sensory sequelae in 15 patients and motor sequelae in 6.

Conclusion: The results of this study describing NSVN presentation, therapeutic management and outcome indicated that acute onset, painful and asymmetrical manifestations are suggestive of NSVN. Half of the patients required immunosuppressive agents because of relapsing and/or refractory disease. Sensory and motor sequelae were common, suggesting that early diagnosis and initiation of therapy are critical.

Systemic Inflammatory and Autoimmune Manifestations Associated with Myelodysplastic Syndrome: A French Multicenter Retrospective Study. Arsen E. Meranian1, Eric Grignano2, Thorsten Braun3, Olivier De-Caux4, Eric Liozon5, Nathalie Costedoat-Chalumeau6, Jean Emmanuel Kahn7, Mohamed Hamidou8, Geraldine Falgarone9, Olivier Lorholtry10, Sophie Park11, Zahir Amoura12, A. Mathian13, Bruno Gombert14, Christian Rose15, Xavier Puechal16, David Lanay17, Guillaume Denis18, Bertrand Lioger19, Anne Laure Buchdahl20, Sophie georgin Lavallie21, Francois Montestruc22, Mohammed Omouri23, Julien Rossignol24, Jean Marc Ziza25, Pascal Catelas26, Serge Madaule27, Benoît de Waziers28, Nathalie Mora29, Sébastien Sehillat30, Hélène Raffray31, Eric Toungou32, Jean-Charles Piette33, Claude Gardin34, Lionel A Des35, Pierre Fenaux36 and Olivier Fain37.

Background: Systemic Inflammatory and Autoimmune Manifestations (SAID) are frequently observed in patients with myelodysplastic syndrome (MDS). The aim of this study was to describe the characteristics, treatment, and outcomes of SAID in a large cohort of patients with MDS.

Methods: A retrospective study was conducted in 35 French hematologic centers. Patients with both MDS and SAID were included. The diagnosis of SAID was based on the revised International Working Party criteria for SAID in 2010. The outcomes were evaluated at the last follow-up.

Results: 123 patients with both MDS and SAID (mean age, 70 ± 13 years; 41 females and 82 males) were included. The baseline characteristics in table 1 are summarized. The incidence of SAID was 66% of cases. The most common SAID were inflammatory arthritis in 28 cases (23%), neutrophilic disorders in 12 cases (10%) and unclassified in 13 cases (11%). Complete diagnostic SAID criteria were fulfilled in 66% of cases, remained incomplete.
in 21% and SAID was unclassified in the remaining patients. The diagnosis of SAID and MDS was concomitant in 38 (31%) cases, diagnosis of SAID preceded MDS in 46 (37%) cases and was made after MDS in 39 (32%) cases, with the time between the diagnoses of the 2 diseases being 8.6±52 months. A part from significant association between Chronic myelomonocytic leukemia (CMML) and systemic vasculitis (p=0.0024), no correlation was seen between specific types of SAID and of MDS. A response to SAID first line treatment (mainly steroids), was observed in 63% of the 116 treated cases, including 80% for steroids alone. A second-line treatment was required for steroid dependence or relapse in 48% of the patients. Among treated patients who received biologic targeted treatments at any time (n=27), overall response of SAID (partial or complete) was noted in 9/20 (45%) patients. Among 16 patients treated by azacytidine for their MDS, SAID remission was seen at 3 months in 7/16 (44%) of the cases, with a significant decrease of acute-phase reactants and steroid amounts required. At last follow-up, 37/70 (53%) patients were in complete or partial remission of SAID, and among patients who received biologic targeted treatments at any time (n=27), overall response of SAID (partial or complete) was noted in 9/20 (45%) patients. Among patients who received biologic targeted treatments at any time (n=27), overall response of SAID (partial or complete) was noted in 9/20 (45%) patients.

Conclusion: The spectrum of SAID associated to MDS is variable, many cases remain difficult to classify. Presence of SAID has no impact on the overall survival of MDS patients. Azacitidine can improve SAID in 75% of the patients. Because of frequent steroid dependence and relapse of SAID, better therapeutic strategies with biological targeted drugs are required, while larger use of MDS specific drugs like azacitidine must be assessed prospectively.

**Cost-Efficacy of Adding Etanercpt to Sulfasalazine and Hydroxychloroquine to Methotrexate Therapy: A Randomized Noninferiority Trial.**

**Background/Purpose:** To estimate the incremental cost-effectiveness of etanercept plus methotrexate versus a triple regimen of disease-modifying anti-rheumatic drugs (methotrexate, sulfasalazine, and hydroxychloroquine) over 24 weeks and 48 weeks in patients with active rheumatoid arthritis despite methotrexate therapy (RACAT).

**Methods:** In this double blind, noninferiority trial 353 patients were randomized to etanercept plus methotrexate or a triple regimen. After 24 weeks of treatment patients not achieving a DA28 improvement of 1.2 were switched in a blinded fashion to the other therapy. Quality Adjusted Life Years (QALYs) were estimated using US societal values from the EQ-5D instrument which was measured every 24 weeks. Costs of drugs, hospitalizations, procedures, tests, visits and lost productivity were prospectively tracked and monetized from a societal perspective in 2014 US dollars. Incremental cost-effectiveness ratios were calculated using standard procedures assuming an intent-to-treat analysis, with missing data analyzed using multiple imputation and uncertainty assessed using bootstrapping.

**Results:** Both strategies showed significant improvements in EQ-5D, with etanercept providing marginally more accumulated QALYs (0.358 vs 0.354 over 24 weeks, and 0.742 vs 0.726 over 48 weeks for etanercept and triple regimen strategies respectively). The etanercept strategy accumulated...
substantially higher drug costs even considering the switches between treatments at 24 weeks ($11,286 vs $369 cumulative costs from 0 to 24 weeks, and $19,625 vs $3,721 cumulative costs from 0 to 48 weeks for etanercept and triple regimen respectively). The differences in other health care and productivity costs across strategies were negligible. The resultant incremental cost-effectiveness ratios for etanercept vs. triple regimen were $11,981 vs $1,245 cumulative costs from 0 to 24 weeks and $21,537 vs $6,358 cumulative costs from 0 to 48 weeks.

Conclusion: This economic evaluation based on a prospective tracking of resource use and QALY measurement in a blinded, randomized trial demonstrates that the additional costs associated with using etanercept prior to a triple regimen does not provide good value for money at generally acceptable willingness to pay thresholds. A limitation of the study is its short time frame. However, even when considering the long-term perspective, since the incremental benefits are so small, even under the most optimistic scenarios imaginable, etanercept has only a small probability of being cost-effective compared to triple therapy. Given the opportunity cost associated with time off work and health care spending, adapting a triple regimen prior to etanercept would free up scarce health dollars for use on alternative health care interventions that provide greater health benefits.

**2782**

**Background/Purpose:** Anti-citrullinated protein antibodies (ACPAs) are highly specific for rheumatoid arthritis (RA) and also believed to play a pathogenic role in RA. Anti-citrullinated peptides from CCP-negative RA patients, but none from the CCP-negative RA patient or healthy donors (p = 0.0015). About 19.5% of circulating plasmablast-derived recombinant antibodies from CCP-positive RA patients, but none from the CCP-negative RA patient or healthy donors, specifically recognized citrullinated RA autoantigens (p = 0.0001). The immunoglobulin genes encoding these ACPAs were highly mutated with increased replacement/site mutation ratios, suggesting that the generation of ACPAs involved active antigen selection. Interestingly, 63% of these ACPAs cross-reacted with the outer membrane antigens and/or citrullinated enolase from P. gingivalis. Germ-line reversions of some ACPAs completely eliminated their reactivity to citrullinated RA autoantigens but retained their reactivity to P. gingivalis antigens.

**Conclusion:** These results suggest that circulating plasmablasts in RA patients produce ACPAs and this process may be, in part, initiated by the anti-P. gingivalis immune responses.

Mice lacking MyD88 do not develop swelling or allodynia (AUC 2.6, NanoString™ nCounter™ analysis of 516 immune genes in the spinal cords). Presence of BMLs 79% 0.92 (0.56, 1.49), examined the development of arthritis and persistent pain in mice pathways. In order to further understand the role of TLR signaling, we unique in signaling through both MyD88-dependent and independent TLR4 showed an attenuation of the late phase of pain. This receptor is of arthritis. Rather than developing persistent pain, animals deficient in persistent pain despite adequate treatment of synovitis. There is a need be attributed solely to increased TNF or IFN expression. The innate and adaptive immune systems appear to have different than the WT mice (AUC 12.2). Disclosure: S. Woller, None; C. Ocheltree, None; L. A. Bradney, None; E. K. Quinn, None; L. Frey-Law, None.

Contribution at the Spinal Level of Innate and Adaptive Immunity to the 2784

Background/Purpose: Individuals with arthritis frequently develop persistent pain despite adequate treatment of synovitis. There is a need to better understand the mechanisms underlying pain occurring with arthritis. Recently, it has been shown that Toll-like receptor 4 (TLR4) mediates the transition from acute to chronic pain in a murine model of arthritis. Rather than developing persistent pain, animals deficient in TLR4 showed an attenuation of the late phase of pain. This receptor is unique in signaling through both MyD88-dependent and independent pathways. In order to further understand the role of TLR signaling, we examined the development of arthritis and persistent pain in mice deficient in these adaptor proteins.

Methods: Adult arthritic K/BxN mice were bled and the sera pooled. One ml of the pooled sera was injected into recipient mice on Days 0 and 2.

Results: As shown previously, WT mice develop a persistent increase in inflammation. The innate and adaptive immune systems appear to have distinct roles in the development of the chronic pain state, and this pain cannot be attributed solely to increased TNF or IFNγ transcription.

J joint Specific Positional Differences in Coding and Noncoding Transcription of Synovial Fibroblasts As a Determinant of the Susceptibility of Synovial Joints to Rheumatoid Arthritis. Caroline Ospelet1, Maria Armaka2, Giancarlo Russo3, Anna Bratus4, Michiel Trenkmann5, Emmanuel Krouzakis1, Christoph Kolling2, Renate E. Gay6, George Kollias6, Steffen Gay7 and Moja Frank Bertocci1. 1Center of Experimental Rheumatology, University Hospital Zurich, Zurich, Zurich, Switzerland; 2Biomedical Sciences Research Center ‘Alexandros Fleming’, Vani, Greece; 3Functional Genomics Center Zurich, ETH Zurich and University of Zurich, Zurich, Zurich, Switzerland; 4Schulthess Clinic, Zurich, Switzerland.

Background/Purpose: The molecular mechanisms underlying the topographic differences in the susceptibility of synovial joints to develop rheumatoid arthritis (RA) are unknown. Positional embryonic expression of Hox genes along proximal-distal and anterior-posterior body axes is critical for proper limb development. A dult skin fibroblasts retain the positional embryonic Hox code and exhibit major anatomic differences in their transcriptome, defining their unique positional identities. Synovial fibroblasts (SF) in the joints of RA patients drive joint destruction and inflammation locally. We hypothesized that SF from different joints show a joint specific, positional gene expression pattern, which can predispose joints to develop certain types of arthritis, like RA or osteoarthritis (OA).

Methods: SF were derived from knees, shoulders and metacarpophalangeal joints (MCPs) of RA and OA patients (n=9 each) undergoing joint replacement surgery. SF were obtained also from front paws, ankles and knees of wildtype (wt) and TNF transgenic (TNFtg) mice (n=7 each). Total RNA was extracted and RNA sequencing was performed with the Illumina HiSeq 2000 sequencing system following by hierarchical clustering. Functional annotation clustering of mRNAs was done using Database for Annotation, Visualization, and Integrated Discovery (DAVID). Positionally expressed RNAs were validated by qPCR.

Results: Unsupervised hierarchical cluster analysis showed clustering of SF according to anatomic joint localization rather than disease. The positional embryonic Hox code was retained in SF, clearly differentiating between different joints. Among the Hox cluster residing long noncoding RNAs, HOTTIP was expressed in distal, MCP-derived SF and HOTAIR in posterior, knee-derived SF. Several positionaly expressed mRNAs, e.g.HOXA8 and HOXD13, were differentially expressed in MCP-derived RA and OA SF. DAVID analysis showed positional enrichment of G0TERM limb development, anterior/posterior patterning, cartilage development, extraradicular region part, cell adhesion, regulation of transcription. While some outliers were found when clustering was based on mRNA expression, clustering of SF into knee, shoulder and MCPs was perfect when based on miR expression. For example, miR-24 was positionally expressed in shoulder, miR-34c in MCP, and miR-137 in knee-derived SF, irrespective of disease. The positional expression of these miRs was confirmed in wt and TNFtg mice. Interestingly, miR-171 and miR-146a were positionally expressed in MCPs of OA, but not of RA patients. These miRs were indeed positional also in wt mice but their MCP specific expression in humans correlated to ankle specific expression in wt mice. In addition, their expression was significantly changed in ankles of TNFtg compared to wt mice.

Conclusion: SF from joints of different anatomic sites exhibit particularly different miRNA and miR expression patterns suggesting that functionally unique subsets of SF populate different joints. The existence of positionally imprinted “risk” signatures of SF may account for the susceptibility of certain synovial joints to develop RA in humans and mice and may have major implications for synovial disease pathways operating early in RA.

2786

Background/Purpose: Idiopathic aortitis is a rare diagnosis that may occur in the context of a primary systemic vasculitis, as part of a systemic autoimmune disease, or in isolation. In patients with focal isolated aortitis...
FIA), surgery alone may be curative; however, new vascular lesions have been reported to develop in between 5-47% of cases. The risk of progression to systemic disease and optimal management strategy for FIA patients is uncertain.

**Methods:** Patients with biopsy-proven aortitis, diagnosed following thoracic aortic surgery at the Cleveland Clinic between 1996 and 2012, were retrospectively reviewed. Patients were classified into clinical subgroups [Giant cell arteritis (GCA), Takayasu’s arteritis (TAK), Focal Isolated Aortitis (FIA) or Other] at the time of surgery using pre-defined criteria. Symptoms, laboratory and imaging results were recorded at surgery and over time using a standardized database. Patients with FIA at surgery were followed for progression to systemic disease and outcomes of clinical subgroups were compared.

**Results:** Of 7,551 patients who underwent thoracic aortic surgery between 1996–2012, 196 patients with biopsy-proven aortitis were identified for review. Median age at surgery was 69 years (range 15–88) and 67% were female. At the time of surgery, 129 (65.8%) patients met criteria for FIA, 42 (21.4%) for GCA, 14 (7.1%) for TAK, and 11 (5.6%) for Other. A minimum of 6 months of clinical follow-up was available for 73 FIA patients. During follow-up (median 45 months, range 6–201 months), 1473 (19.2%) FIA patients developed symptoms of systemic disease, 17/40 (42.5%) developed elevated inflammatory markers, 29/65 (44.6%) developed new vascular lesions on imaging, 30/73 (41.1%) required a second vascular surgery, 7/15 (46.7%) dissected and 9 died (12.3%). Ultimately 23 of 73 (31.5%) with FIA progressed to have features of a systemic disease: 21 GCA, 1 TAK, and 1 Other. When compared to patients with known systemic disease at surgery, patients with FIA were less likely to develop symptoms (p=0.01) but no different with respect to development of elevated inflammatory markers (p=0.19), new vascular lesions by imaging (p=0.92), need for further vascular surgery (p=0.84), dissection (p=0.40) or death (p=0.76) over time. Only 12 patients without symptoms at surgery received immunosuppressive therapy post-operatively. Over time, 0/11 treated FIA patients with follow-up imaging developed aneurysms, but 2 (18.2%) developed new stenoses. Among the 54 untreated FIA patients with imaging available, 27 (50%) developed new vascular lesions (23 aneurysms and 5 stenoses.) A additional tissue obtained after subsequent surgery in 2 untreated FIA patients revealed persistent inflammation in the distal aorta.

**Conclusion:** Over time, nearly one third of patients classified as FIA at the time of surgery progressed to have features of a systemic autoimmune disease. Patients with FIA are less likely to develop overt symptoms, but equally likely to develop elevated inflammatory markers or new vascular lesions on imaging when compared to GCA, TAK and Others. These patients require regular clinical follow-up and serial imaging to assess for progression.

**Identification of Urinary Biomarkers for Lupus Nephritis.** Carolina Landolt-Marticorena1, Stephanie Prokop2, Heather Reich3, J. Idrees, None; C. Avila-Casado2, Paul R. Fortin4, Paul Boutros5 and Joan Wither, None.

**Background/Setting:** The California Lupus Surveillance Project (CLSP) is a population-based registry designed to determine the incidence and prevalence of SLE in San Francisco County, California. Sources of cases included hospitals, rheumatologists, nephrologists, commercial laboratories, and state population databases. Over 15,000 potential SLE patients were identified after the initial queries, and trained abstractors performed detailed medical chart reviews on the 5,500 patients who met the catchment criteria of residence in San Francisco County within the years of 2007–2009. Cases were defined as patients with documentation of ≥ 4/11 of the ACR Classification Criteria for SLE. Using SAS 9.3, we calculated prevalence and incidence rates and associated 95% confidence intervals (CI) and denominators for all rates were obtained from the U.S. Census data (revised 2007). Preliminary estimates of prevalence and incidence of systemic lupus erythematosus (SLE) in the United States have varied widely.

**Methods:** The CLSP is a population-based registry designed to determine the incidence and prevalence of SLE in the United States. The California Lupus Surveillance Project (CLSP) is part of a national effort funded by the Centers for Disease Control and Prevention (CDC) to develop more credible estimates of incidence and prevalence of SLE, with a special focus on Hispanics and Asians.

**Background/Setting:** The CLSP is a population-based registry designed to determine the incidence and prevalence of SLE in the United States. The California Lupus Surveillance Project (CLSP) is part of a national effort funded by the Centers for Disease Control and Prevention (CDC) to develop more credible estimates of incidence and prevalence of SLE, with a special focus on Hispanics and Asians.

**Results:** Preliminary overall crude prevalence and incidence of SLE in San Francisco County were 90.4/100,000 and 5.1/100,000 respectively. The highest prevalence of disease was observed in Black women (430.6/100,000), followed by Hispanic and Asian (163.8/100,000 and 158.9/100,000, respectively), and White (111.3/100,000) women (Table I).

Conclusion: The CLSP uses more complete case finding methods to provide current estimates of prevalence and incidence in a racially and ethnically diverse population. Racial and ethnic disparities in SLE were confirmed with the highest burden of disease in Black women, followed by Hispanic and Asians, and, finally, White women.

2789 Medical Marijuana Related Outcomes in Patients with Systemic Lupus Erythematosus. Basmah Jalil1, Wilmer Sibbit Jr2, Romy Cabacanguan3, Clifford Qualls4, Arthur Bankhurst5 and Roderick Fields3. 1University of New Mexico, Albuquerque, NM, 2University of New Mexico HSC, Albuquerque, NM, 3UNM, Albuquerque, NM, 4University of NM Med Ctr, Albuquerque, NM, 5University of New Mexico School of Medicine, Albuquerque, NM.

Background/Purpose: Medical cannabis is used extensively in the United States, usually in the form of smoked marijuana. There is growing research regarding the immunomodulatory effects of cannabinoids and the cannabinoid receptor system as a possible therapeutic target. Despite the increasing use of medical marijuana, almost all studies report short-term subjective effects of medical cannabis with little to no real outcome data in medical disease and systemic lupus erythematosus (SLE) in particular. Randomized, controlled trials of smoked cannabis are generally considered ethically problematic. This study determined whether cannabis was associated with important outcomes in SLE, including mortality and morbidity.

Methods: This is an analysis of a prospective de-identified 5 year longitudinal outcome study of a cohort of SLE patients at the University of New Mexico with a sample size of 276 patients with 30.4% using marijuana and 69.5% with no marijuana use. All patients had signed informed consent, but additional IRB approval was obtained prior to analyzing the de-identified database in relation to cannabis. Inclusion criteria were any patient with SLE, age 18-80. Exclusion criteria were any patient with a diagnosis other than SLE, age < 18 years, age > 80 years. The population sample was diverse and included all social and ethnic backgrounds, with Hispanics and Whites being the dominant participants. This analysis was supported by the University of New Mexico.

Results: 27 patients underwent CMR: mean age 32.4 years, 82% female, 44% black, mean SLEDAI-2K 10.1, 10.4. All CMLD subjects had 2 or more mid cardiac segments with elevated T2 signal (Table 2). The mean T2 signal for mid cardiac segments was elevated compared to 40 historical healthy controls (57.0 ms vs. 5 vs. 54.5 ms ± 2.2; p = 0.010) The mean LV circumferential strain was −15.2% ± 5.4 which is lower than accepted normal values (−20%). SLEDAI-2K scores positively correlated with mean mid cardiac T2 signal (r = 0.57); and mid cardiac maximum T2 signal (r = 0.65). Only 1/27 (7%) patients had positive LGE.

Conclusion: In this cohort of active SLE patients CMR with quantitative T2 mapping identified a high prevalence (44%) of patients with abnormal T2 signal in ≥2 mid cardiac segments, suggesting subclinical myocardial inflammation which may be common in SLE flare. Both mean and mid segment T2 showed correlation with SLE disease activity measured by SLEDAI scores. Mean LV circumferential strain was lower than normal, suggesting impaired LV function. Very few CMR showed evidence of myocardial fibrosis as measured by LGE enhancement. Further study is needed to determine if abnormal quantitative T2 mapping during SLE flare foreshadows longer term CV complications.

Lung Cancer in SLE. Sasha Bernatsky1, Rosalind Ramsey-Goldman2, Michelle Petri3, Murray B. Urowitz4, Dafna D. Gladman5, Edward H. Yelin6, Christine Peschken7, John G. Hanly8, James E. Hansen9, Jean-Francois Boivin10, Lawrence Joseph11, Patrice Christian Raymer12, Maruganka Kale13, Ann E. Clarke14, Systemic Lupus International Collaborating Clinics (SLICC)15. 1McGill University, Montreal, QC, 2Northwestern University, Chicago, IL, 3Johns Hopkins University School of Medicine, Baltimore, MD, 4University of Calgary, Calgary, AB, 5Mcgill University Health Centre, Montreal, QC, 6University of Manitoba, Winnipeg, MB, 7Dalhousie University and Capital Health, Halifax, NS, 8Yale University, New Haven, CT, 9McGill University Health Centre, Montreal, QC, 10RI-McGill Univ Hlth Ctr, Montreal, QC, 11University of Calgary, Calgary, AB, 12Systemic Lupus International Collaborating Clinics (SLICC), ON.

Background/Purpose: Lung cancer is 50% more common in SLE patients than their sex and age-matched counterparts. Our objective was to assess lung cancer risk in SLE, comparing demographics, drug exposures, and disease activity.

Methods: We used data from a very large multi-site international SLE cohort; this preliminary analysis is based on 6 centres: Halifax, Toronto, Montreal, Winnipeg, San Francisco, Baltimore. We used Cox proportional hazards regression to calculate the hazard ratio (HR) for lung cancer risk in SLE, relative to smoking, demographics (sex, age, race/ethnicity and time-dependent drug exposures and cumulative disease activity (based on adjusted mean SLEDAI-2K scores, assessed at baseline and annually). The adjusted mean SLEDAI score was assessed both as a continuous variable and (to aid in interpretation) and categorical. Time zero for the observation interval was the SLE diagnosis, so that our analyses adjusted for SLE duration. We included observation time and lung cancer events occurring after entry into the lupus cohort and up to the time of cohort exit (death, cancer, or date of last visits). Those developing a cancer other than lung during the interval, were censored at that time.

Results: Within the cohort (N=2791), 34 lung cancers (7 male, 27 female) occurred. Versus SLE controls without cancer, lung cancer cases tended to be white (85.3% versus 63.3% in controls), and older at cohort entry (mean 52.3 years, median 52.9; versus mean 38.4, median 36.9 in controls). Among lung cancer cases 61.8% had high disease activity (highest SLEDAI quartile) at baseline (95% CI 43.6, 77.8), in contrast to only 40.1% (95% CI 38.6, 41.5) of SLE patients that went on to remain free of lung cancer. The vast majority (78.8), in contrast to only 40.1% (95% CI 38.6, 41.5) of SLE patients that went on to remain free of lung cancer. The vast majority (78.8, p=0.001) of the lung cancer cases in SLE were ever-smokers, versus 40.7% of the SLE patients who did not develop lung cancer. The drug profiles seemed similar (in terms of steroids, immunomodulators, NSAIDs) in the SLE patients who developed lung cancer versus those who did not (though of note, none had been exposed to cyclophosphamide prior to a lung cancer). In both univariate and multivariate models, the principal factors associated with lung cancer risk were ever smoking and age. The adjusted analyses did suggest a trend for greater cancer risk in SLE patients with higher cumulative disease activity over time (HR 1.81, 90.9, 3.63) although the CI included the null value. The estimated adjusted effects of all drugs were relatively imprecise.

Conclusion: There was a trend for greater cancer risk in SLE patients with higher cumulative disease activity over time, although we saw no definite adverse effects of drugs on lung cancer risk in SLE. In particular we did not note prior cyclophosphamide exposure in the lung cancer cases. However, drug estimates were relatively imprecise. Smoking appears to be the most significant modifiable risk factor for lung cancer in SLE.

A CR Concurrent Abstract Session

Biology and Pathology of Bone and Joint In: Bone Remodeling in Inflammation and Arthritis

Tuesday, November 18, 2014, 2:30 PM–4:00 PM

2792

Methotrexate Prevents Inflammatory Osteolysis By Activation of the Adenosine a2a Receptor (A2AR). Aranzazu Mediero1, Tuere Wilder2 and Bruce N. Cronstein3. 1NYU School of Medicine, New York, NY, 2NYU School of Medicine, Division of Rheumatology, New York, NY.

Background/Purpose: Prior studies demonstrate that adenosine, acting at A2AR, mediates the anti-inflammatory effects of methotrexate (MTX) in models of both acute and chronic inflammation. We have previously reported that adenosine A2AR ligations diminishes wear particle-driven osteolysis. We asked whether MTX treatment could prevent bone resorption due to inflammatory osteolysis.

Methods: MTX (1mg/kg) was administered intraperitoneally to C57Bl/6 mice on a weekly basis starting 2 weeks prior to surgery. Control mice were injected with 0.9% saline. In mice midline sagittal incisions were made over calvaria in 6–8 wk old C57Bl/6 mice. Calvaria were exposed to 20μg of PUL containing 3μg of UHMWPE followed by daily injections of either vehicle (Control and MTX) or ZM241385 1μM (A2AR antagonist) (n=5 each) for 14 days. Xenolight Rediject Bone Probe was injected IV and fluorescence of calvaria measured (IVIS) to assay bone formation. MicroCT and immunohistochemistry for osteoclast and osteoblast markers were performed.

Results: XenoLight imaging revealed an 80±10% increase in bone formation after exposure to MTX when compared to UHMWPE alone (p<0.001, n=5) and ZM241385 completely reversed this effect (11±5% increase vs. control, p=NS, n=5). MicroCT analysis revealed increased porosity in particle-exposed mice that was inhibited by MTX treatment (54±6% decreased compared to saline treatment, p<0.001, n=5) an effect abrogated by ZM241385. MTX significantly increased bone volumnetotal volume (BV/TV) (5.94±0.1 vs 8.68±0.2, p<0.05, BV (5.31±0.3 vs 4.15±0.2, p<0.05, TV: 5.09±0.2 vs 3.76±0.2, p<0.001) and Bone Mineral Density (BMD) (153.75±0.4 vs 144.63±1, p<0.001) when compared to WT, and ZM241385 completely reversed this effect. Histological examination of particle-exposed mouse calvarias demonstrated an inflammatory infiltrate on the bone surface that was significantly reduced by MTX and treatment with ZM241385 completely reversed this effect.

Conclusion: These results indicate that treatment with MTX, a well-tolerated and commonly used anti-inflammatory drug, may provide a novel therapeutic approach to enhance orthopedic implant survival, delaying or eliminating the need for revision arthroplasty surgery.

BM2 Requires TGF-Beta to Induce Osteophytes during Experimental Osteoarthritis. Esmeralda Blaney Davidson1, Arjan Blom2, Arjan van Caam2, Elly Vitters1, Miranda Bennis1, Wim van den Berg2, Fons de Loo3 and Peter van der Kraan1. 1Radboud university medical center, Nijmegen, Netherlands; 2Radboud University Medical Center, Nijmegen, Netherlands; 3Radboud University Medical Center, Nijmegen, Netherlands.

Background/Purpose: Osteophytes are a major hallmark of osteoarthritis (OA). Both TGF-beta and BMP2 can induce osteophytes in murine knee joints. We demonstrated that TGF-beta could induce chondrogenesis in mesenchymal stem cells when BMPs were inhibited but not vice versa. This suggested that BMP2 might require a trigger like TGF-beta to induce initial stages of chondrogenesis. Therefore, we investigated whether BMP2 was still able to induce osteophyte formation in experimental OA when TGF-beta activity was blocked.

Methods: We made a unique transgenic mouse (Col2a1-rtTA-BMP2) expressing BMP2 under control of the Col2a1 promoter, only when exposed to doxycycline (dox) which results in only chondrocytes producing BMP2. These mice were fed dox-food up to 8 weeks to investigate BMP2 effects on osteophyte formation. We induced the DMM-model and investigated whether BMP2 augmented osteophyte formation. We combined the DMM-model with intra-articular injection of an adeno-virus overexpressing TGF-beta-inhibitor LAP with or without dox. Knee joints were isolated 4 weeks after DMM for histology.

Results: There was no significant difference in osteophyte formation between dox and non-dox treated Col2a1-rtTA-BMP2 mice. However, dox treatment increased the number of osteophytes (8.0) during DMM compared to DMM non-dox (4.25). These "new" osteophytes were larger than DMM-induced osteophytes. The lack of osteophytes by dox compared to BMP2 no longer augmented the number of osteophytes during DMM. Strikingly, inhibition of TGF-beta significantly reduced the pace of osteophyte formation. This was completely abolished by the presence of BMP2 restoring the speed of osteophyte formation and maturation.

Conclusion: Our data show that BMP2 is capable of inducing osteophyte formation, but is dependent on an additional trigger to achieve this, as present in OA. In OA conditions, BMP2 can severely aggravate osteophyte formation, both in number and size. However, when TGF-beta is blocked BMP2 is no longer capable of aggravating osteophyte formation during DMM. Strikingly, early inhibition of TGF-beta during OA impared the speed of osteophyte formation, which could be compensated by the presence of BMP2.

Our data show for the first time that BMP2 is dependent on TGF-beta to induce de novo osteophyte formation. This provides novel insight into the mechanism behind osteophyte formation and provides clues for future therapeutic application for osteophyte formation in OA.

Deletion of the Inhibitory Receptor Motif, ITIM, on DC-STAMP Alters Osteoclast Differentiation and Function. Yahui Grace Chiu2, Edward M. Schwartz2, Dongle Li1, Yuxin Xu1, Minsoo Kim1 and Christopher T. Ritchlin1. 1University of Rochester, Rochester, NY; 2University of Rochester Medical Center, Rochester, NY.

Background/Purpose: DC-STAMP (Dendritic Cell-Specific Transmembrane Protein), a β-transmembrane protein essential for cell-to-cell fusion during osteoclast (OC) differentiation, is expressed on the cell surface of OC precursors (OCP). DC-STAMP knock-out (KO) mice form only mononuclear OC and have mild osteopetrosis due to the absence of functional multinucleated OC with bone erosion activity. Previously, we identified an immunoreceptor Tyrosine-based Inhibitory Motif (ITIM) on the cytoplasmic tail of DC-STAMP, which suggested the potential role of DC-STAMP in signaling during osteoclastogenesis. A major hurdle in DC-STAMP research, however, is the absence of a known ligand. To overcome this barrier, we engineered DC-STAMP:rhodopsin chimeric molecules that can be activated by light (photo-activatable). This approach enabled us to investigate the downstream events of DC-STAMP activation, and examine the importance and function of the ITIM in osteoclastogenesis.

Methods: DNA constructs were generated in which the four extracellular domains of DC-STAMP were replaced with the photo-activatable extracellular domains of rhodopsin. The functionality of two DC-STAMP chimeras (WT: original ITIM; TD: ITIM-deleted) was confirmed by: (1) activation of a calcium signal by 505-nm light, a wavelength that specifically excites rhodopsin; and (2) expression of mCherry protein (red), which was fused to the C'-terminus of DC-STAMP during engineering. These 2 chimeras were transfected into either murine 293T cells, or mouse bone marrow-derived macrophages (BMM) isolated from the DC-STAMP KO mice. To assess the role of the ITIM in signaling, we assessed the dynamic intracellular Ca2+ flux known to occur during normal osteoclastogenesis between the WT and TD transfected cells. Bone erosion was assessed by the bone wafer assay.

Results: The studies with the transfected chimeric molecules revealed the following. First, deletion of ITIM on DC-STAMP resulted in a significant and continuous (non-pulsatile) elevation (3-fold > WT DC-STAMP) in the intracellular Ca2+ level after light activation. Second, ITIM-deleted DC-STAMP did not complement the deficiency of cell-cell fusion in DC-STAMP KO cells, which was fully corrected and restored by the WT DC-STAMP. Most cells expressing ITIM-deleted DC-STAMP were unable to fuse, although rare cells with 3 nuclei were observed. Third, in contrast to an even distribution of wild-type DC-STAMP on the cell surface, ITIM-deleted DC-STAMP was expressed on the cell surface in a clustered and punctate distribution fashion. Fourth, bone resorption decreased in cells expressing TD compared to WT DC-STAMP.

Conclusion: Our results suggest that the ITIM on the cytoplasmic tail of DC-STAMP functions (1) to induce pulsatile intracellular Ca2+ flux required for osteoclastogenesis after DC-STAMP activation; (2) to trigger cell-to-cell fusion between OCPs and form multinucleated mature OC; (3) to maintain an even distribution of DC-STAMP on the cell surface; (4) to support bone erosion activity of OC. Blocking the ITIM on DC-STAMP by targeted inhibition might serve as a novel strategy to inhibit pathologic bone resorption by OC in inflammatory and metabolic bone disorders.

Blockade of IL-6R Signaling by Sarilumab Suppressed Circulating Markers of Bone Resorption and Synovial Damage in Rheumatoid Arthritis Patients from a Phase 3, Randomized, Double-Blind, Placebo-Controlled, International Study. Anita Boyapati1, Jennifer K. M. Teoh1, Emanuella Cousin2, Ling Ca3, Janet van Aalsberg1, Jennifer D Hamilton2, Neil Graham1, Tanya M om Tahanen1 and Stefano Fiore2. 1Regeneron Pharmaceuticals, Inc., Tarrytown, NY; 2Sanofi R&D, France, Chilly-Mazarin, France; 3Sanofi R&D, China, Beijing, China; 4Sanofi, Bridgewater, NJ.

Disclosure: Y. G. Chiu, None; E. M. Schwartz, Johnson & Johnson, 5, NIAMS-NIH, 2; D. Li, None; Y. Xu, None; M. Kim, None; C. T. Ritchlin, Eli Lilly and Company, 9, Eli Lilly and Company, 5.
Background/Purpose: Rheumatoid arthritis (RA) patients develop bone and joint damage due to chronic inflammation mediated by critical cytokines, eg, IL-6. Pre-clinical studies have implicated IL-6 signaling in regulation of osteoclasts and fibroblast-like synoviocytes (FLS) to increase levels of bone resorptive molecules like receptor activated NF kB ligand (RANKL) and joint destructive proteins, such as matrix metalloproteinases (MMPs). Blockade of IL-6R signaling by sarilumab significantly reduced structural damage in RA patients, as measured by the modified van der Heijde total Sharp Score, including the erosion score and joint space narrowing components in the Phase 3 part of the MOBILITY study (NCT01671363). Most common TEAEs included infections and injection site reactions. A higher incidence of serious infections was observed with sarilumab. Lab abnormalities included decreases in neutrophils and increases in transaminases and lipids. To elucidate mechanisms of clinical reduction of bone and joint damage by sarilumab, we evaluated a panel of serum markers associated with bone resorption (RANKL and osteoprotegerin [OPG]), bone turnover (CTX-1 and C1M), osteoblast formation (osteocalcin [OC]), synovium (MMP-3 and C3M) and cartilage degradation (C2M) in patients enrolled in MOBILITY B. Methods: Sera were analyzed from 128 patients treated with placebo (Pbo) + methotrexate (MTX), and 131 patients receiving subcutaneous 200 mg sarilumab every other week (q2w) + MTX. Serum biomarkers levels were measured by ELISA. All biomarkers were analyzed at baseline and post-treatment at Wks 2 and 24, with the exceptions of C2M and OC, which were analyzed at baseline, Wks 24 and 52 post-treatment. A mixed effect model with repeated measures on % change from baseline (after rank transformation) was performed for all biomarkers (ANOVA-type method). Tests were compared at each visit. For samples above the limit of quantitation (LOQ), the LOQ was used in analyses, for samples below the LOQ, half the LOQ was used. Results: Sarilumab + MTX treatment significantly reduced levels of MMP-3 and MMP generated fragments of collagen type 1 and type 3 (C1M and C3M) compared to Pbo + MTX at all timepoints analyzed (Table). RA RANKL levels were also reduced at Wk 24 in the sarilumab + MTX group, however, approximately 15% of values were above the LOQ. In contrast, C2M increased from baseline in the sarilumab 200 mg q2w + MTX group compared to Pbo + MTX but did not reach significance (Wk 52, p = 0.0571). Conclusion: Sarilumab reduced bone resorption and joint damage markers, and increased OC, a marker of bone formation, in RA patients. This is the first report that IL-6 inhibition leads to RANKL reduction in RA patients. This data supports a mechanism whereby increased IL-6 signaling promotes structural damage through osteoclasts and FLS and by reducing osteoblast bone formation. Disclosure: A. 2797 Anti-Citrullinated Proteins Antibodies Promotes Osteoclastogenesis and Bone Destruction in Rheumatoid Arthritis. A Kilian Krishnamurthy1, Vijay Joshua1, Heidy Wahanna2, Caia Cerqueira2, Lars Klaren2, Vivianne Malmström2, Jimmy Y Teberberg2 and Ana C Alattina2. 1Rheumatology Unit, Karolinska University Hospital, Stockholm, Sweden; 2Karolinska Institute, Stockholm, Sweden, 3Rheumatology Unit, Karolinska University Hospital, Solna, Karolinska Institute, Stockholm, Sweden.

Background/Purpose: Presence of anti-citrullinated protein antibodies (ACPA) is a major risk factor for bone erosion in rheumatoid arthritis (RA) and antibodies against modified citrullinated vimentin induce osteoclast (OC) formation from monocytes. Besides monocytes, dendritic cells (DC) are potential osteoclast precursors that may be aimed to further characterize DC derived osteoclastogenesis and to explore the effect of pooled and individual monoclonal ACPA on this pathway. Methods: ACPA positive and negative IgGs were isolated from synovial fluid (SF, n = 26) and peripheral blood (PB, n = 38) samples of RA patients. CD14+ monocytes from PB of ACPA+ RA patients and healthy individuals were first cultured in the presence of GM-CSF and IL-4 to generate DC or M-CSF to generate M-0, and then further differentiated to OC in the presence of RANKL and M-CSF. In parallel, cells were grown on osteoassay surfaces and bone resorption area was quantified by computer assisted image analysis. In house generated anti-citrullinated monoclonal antibodies obtained from SF B-cells were also tested. Cytokines were measured by cytokometric bead arrays in cultures supernatants. Mass spectrometry analysis was performed on different stages of differentiation of DC derived OC. Immunohistochemistry (IHC) was used to stain the OCs with biotinylated ACPA IgG and monoclonal anti-citrullinated proteins antibodies. The effect of PAD inhibition (C1.amidine) and IL-8 inhibition was tested in the osteoclasts cultures. Results: SF derived ACPA's enhanced osteoclastogenesis and bone resorption from both DC (fold increase of 1.6±0.2 for osteoclasts number and 2.0±0.3 for bone resorption area) and M-0 (fold increase of 1.6±0.4 for osteoclasts number and 2.0±0.8 for bone resorption area) of healthy donors. Similar effect was observed when the precursor cells were derived from ACPA+ RA patients in both DC (fold increase of 2.3±0.9 for osteoclasts number and 2.6±0.1 for bone resorption area) and M-0 (fold increase of 1.8±0.6 for osteoclasts number and 2.3±0.7 for bone resorption) assays. PB
derived ACPAs were equally effective with SF ACPAs. Principal component analysis confirmed distinct proteomic profiles during osteoclasts maturation from DC and Mφ, respectively. Vimentin significantly increased during DC-OC maturation, with citrullinated vimentin peptides detectable in mature osteoclasts. Increased osteoclastogenesis was associated with significantly higher levels of IL-8 levels in cultures supernatants of both DC (fold increase of 2.4±0.5) and Mφ (fold increase of 2.0±0.5). Two of the tested anti-citrullinated monoclonal antibodies had similar effects, while a third one had no such effect. Fab fragments of these monoclonal antibodies retained similar effects. Binding of these antibodies on OC was confirmed using IHC. Both PAD activity and IL-8 appear to be required for ACPA effects.

Conclusion: SF and PB derived ACPA IgGs with broad specificities enhanced osteoclastogenesis from both DC and Mφ. This effect appears to be restricted to certain ACPAs specificities and at least partially mediated through a Fab mediated mechanism.

The Differential Impact of Obesity on the Pathogenesis of RA or Preclinical Models is Contingent on the Disease Status. Zhenlong Chen1, Seung-jae Kim2, Abdul Essani3, Michael V. Volin4, Suncica Volkov3, William Swedler1, Shiva Arami1, Giamila Fantuzzi1, Nadera J. Swiezi1 and Shiva Shahraha1. 1University of Illinois at Chicago, Chicago, IL, 2Chicago College of Osteopathic Medicine Midwestern University, Downers Grove, IL.

Background/Purpose: Studies were performed to determine the significance of obesity in the pathogenesis of rheumatoid arthritis (RA) and experimental arthritides models.

Methods: Chronic and acute preclinical models of arthritis were utilized to examine the impact of obesity on different disease stages. Inflammatory mediators were identified in the adipose tissue of mice with obesity and arthritis using ELISA. Role of IL-8/MIP2 was investigated in disease onset employing neutrophil chemotaxis. RA and mouse myeloid cells as well as ankle joints from preclinical arthritis models were utilized to assess the importance of proinflammatory M1 macrophage differentiation in disease remission using real-time RT-PCR, histology and Western blotting.

Results: We document that early onset of collagen induced arthritis (CIA) was impaired by high fat diet (HFD) on days 26, 28 and 30 post onset compared to mice fed with regular diet (RD). To elucidate the mechanism by which obesity affects the early stage of RA, inflammatory factors were quantified in adipose condition media extracted from RA synovial tissue and obese mouse gonadal adipose tissue. We uncovered that a great number of neutrophil (CXCL1, CXCL5 and IL-8/MIP2) and monocyte chemokine attractants (TNF-a, IL-17, IL-1β, CCL2) are present in RA and mouse adipose condition media, however levels of IL-8/MIP2 exceeded all other factors. We found that early arthritis exacerbated by obesity is due to elevated IL-8/MIP2 protein levels in the obese joint, as blockade of IL-8/MIP2 dysregulates neutrophil chemokinesis in response to RA and mouse adipose media, in contrast, neutralization of CXCL1 and CXCL5 was ineffective in this process. To elucidate the effect of obesity on arthritis progression, we chose to utilize the TLR4 induced arthritis model. We found that in the first 48h, TLR4 driven joint inflammation progresses similarly in obese and lean mice. Thereafter while arthritis resolves in the lean mice, ankle swelling is sustained in the obese mice at 72h post LPS injection. Histological studies confirm that mice on HFD have markedly greater joint inflammation and lining thickness compared to RD group. Corroborating with the higher levels of monocyte chemoattractants detected in the obese mice (TNF-a, IL-17, CCL20 and IL-6), joint myeloid cell recruitment was potentiated in the HFD arthritic mice compared to RD group. To better understand how obesity prolongs arthritis, joint myeloid cell phenotype was evaluated in the obese and the lean arthritic mice. We show that the obese arthritic mice, predominately express iNOS+ M1 macrophages, while inOS+ cells are reduced and Arginase++ M2 macrophages are strongly expressed in the lean mice. Consistently, employing RA and mouse adipose condition media we show that RA or mouse naive cells can be transformed into M1 macrophages. Hence, our result exhibit that obesity can sustain arthritis by reprogramming the newly recruited joint myeloid cells into proinflammation M1 macrophages.

Conclusion: We show for the first time that early and late RA is impacted by obesity through differential mechanism of function.

A CR Concurrent Abstract Session

Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis I

Tuesday, November 18, 2014, 2:30 PM–4:00 PM
**Background/Purpose:** Psoriatic Arthritis (PsA) is a common, chronic immune-mediated inflammatory disease, characterised by synovitis, progressive destruction of articular cartilage/bone, and is associated with psoriasis. Janus Kinase and Signal Transducer and Activator of Transcription (JAK/STAT), a critical signalling pathway involved in inflammatory mechanisms, has been implicated in the pathogenesis of PsA. This study was to examine the mechanistic effect of Tofacitinib (a novel JAK inhibitor CP-690,550) on pro-inflammatory pathways using ex vivo and in vivo models of PsA.

**Methods:** PsA whole tissue synovial explants cultures were established from PsA biopsies obtained under direct visualisation at arthroscopy. This explant model maintains the architecture and cell-cell contact of the synovial tissue, spontaneously releases pro-inflammatory mediators and therefore closely reflects the in vivo inflamed microenvironment. Primary PsA synovial fibroblasts (PsASFC) were also isolated from PsA synovial biopsies. Phospho-STAT-3 (p-STAT3), phospho-STAT1 (p-STAT1), Suppressor of Cytokine Signal (SOCS3) and Protein Inhibitor of Activated STAT 3 (PIAS3) expression were quantified by Western Blot in PsA synovial explants and PsASFC following culture with Tofacitinib (1µM) or vehicle control. Cytokine expression of IL-6, IL-8 and IL-10 in ex vivo culture synovial explants in response to Tofacitinib (0.5µM-1µM) were assessed by ELISA. Furthermore, the effect of Tofacitinib (0.5µM-1µM) on PsASFC migration, invasion, matrigel network formation and MMP2/9 were quantified by wound repair assays, transwell invasion chambers and zymography.

**Results:** Tofacitinib significantly decreased p-STAT3 and p-STAT1 expression in PsA synovial tissue explants cultures ex vivo and in primary PsASFC (p<0.05). In contrast Tofacitinib induced SOCS3 and PIAS3 expression in both models (p<0.05). In parallel Tofacitinib significantly decreased spontaneous secretion of IL-6 (p<0.05), IL-8 (p<0.05) and induced IL-10 (p<0.05) expression in PsA explant cultures. Functional IL-38 was decreased by siRNA-mediated knockdown of NIK in EC as compared to the non-targeting siRNA controls. LT and LIGHT induced sprout formation was significantly decreased by siRNA-mediated knockdown of NIK in EC as compared to the non-targeting siRNA controls.

**Conclusion:** This is the first study to demonstrate Jak/STAT signaling and the effect of Tofacitinib on these pathways in PsA synovial tissue and primary PsA synovial fibroblasts. Tofacitinib mediated specific JAK-STAT signaling components, inhibited key pro-inflammatory cytokines and invasion/migrational mechanisms. Thus this data further supports the use of JAK-STAT inhibition as a potential therapeutic agent for the treatment of PsA.

**Background/Purpose:** Non-Canonical NF-kappab Signaling Promotes Angiogenesis in a Novel 3D Spheroid Model of Rheumatoid Arthritis Synovial Inflammation. Christisa X. Maracle1, Boy Helder1, Aei-Ri Noort1, Corine van der Horst2, and Sander W. Tas2.1Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands; 2Athenogene BV, Amsterdam, Netherlands.

**Methods:** We developed a novel 3 dimensional (3D) model in which human umbilical cord vein EC and RA SFSF were labeled with green or orange cell tracker dye, respectively, and incubated overnight to form spheroids. Subsequently, the spheroids were harvested and plated in collagen solution, and medium with or without lymphotixin α1β2 (LT) or LIGHT (both stimuli that induce non-canonical NF-κB signaling via the lymphotixin beta receptor (LTβR)) or pro-angiogenic growth factors (bFGF/VEGF) was added. After 48 hours, spheroids were fixed and imaged through confocal microscopy. Cumulative EC sprout number and the number of sprouts was quantified using Leica QWin Plus software. To demonstrate NIK dependency of this process, EC were transfected with non-targeting or NIK targeting siRNA before incorporation into the model and subsequent sprout formation was quantified.

**Results:** Confocal analysis of the 3D model showed spheroids containing HUVEC and RA SFSF formed sprouts under all conditions. Both LT and LIGHT caused significant increases in cumulative sprout length (p<0.05). Interestingly, the total number of sprouts formed by each spheroid also increased significantly. LT and LIGHT induced sprout formation was significantly decreased by siRNA-mediated knockdown of NIK in EC as compared to the non-targeting siRNA controls.

**Conclusion:** Our novel 3D model demonstrates that activation of the non-canonical pathway induces angiogenesis in spheroids of EC and RA SFSF and that this process is strictly NIK dependent. This suggests that NIK targeting therapeutic might be able to reduce pathological angiogenesis in synovial inflammation and possibly halt disease progression. Further studies to test this, including the use of small molecule pharmacological NIK inhibitors, are currently underway. Of interest, the current 3D model is also optimized to include different subsets of immune cells in order to study their contributions to inflammation-induced angiogenesis, which makes this model a valuable tool for future studies.
**Methotrexate Impacts the Effects of Tofacitinib, but Not Tocilizumab, on Clinically Relevant Biomarkers in Human Primary Cell-Based BioMAP® Disease Models: Can We Utilize in Vitro Models to Predict Clinical Outcomes?**

Alison O'Mahony, Ellen L. Berg, Xitong Li, Markus R. John, Kandeepan Ganeshalingam, and Ernest H. Choy.

**Background/Purpose:** A number of trials have shown that adding MTX benefits some, but not all, biologies and small molecules to treat RA. Specifically, though treatment of RA with an anti-TNF + MTX has been shown to be more beneficial than with the biologic alone, the same was not consistently observed with tocilizumab (TCZ) + MTX. Thus, it remains a challenge to determine whether cotreatment with MTX is a better option for patients. We have previously reported that BioMAP activities detected with TCZ alone were highly similar to those of TCZ + MTX, whereas the effects of adalimumab (ADA) alone differed from those of ADA + MTX. Here we evaluate whether MTX alters the pattern of BioMAP activities of tofacitinib (TOF) in order to predict whether the effects of this drug can be modulated by cotreatment with MTX.

**Methods:** Human primary cell-based BioMAP disease models were used to generate phenotypic activity profiles for compounds alone and in combination with MTX at concentrations that cover their clinical Cmax ranges. TCZ, 200 mg/mL; TOF, 11 μM; TOF, 0.12 μM; MTX, 10 μM. Agents and combinations were tested under standard and soluble interleukin-6 receptor-stimulated conditions. Changes in protein-based, clinically relevant end points (biomarkers) and proliferation were evaluated by t-test and other statistical methods to determine whether activities of the combinations differed from those of the individual agents.

**Results:** Several activities detected with TOF + MTX or TOF + MTX were statistically significantly different (p < 0.01) from those of TOF or TOF profiled alone. Cytokine and chemokine levels (M-CSF, G-CSF), inflammation markers (VCAM-1, E-selectin, and IP-10), and tissue-remodeling activities (thrombomodulin and PAI-1) were all modulated differently by TOF + MTX vs TOF alone. In contrast, the profile of TCZ + MTX was not significantly different from that of TCZ alone, with only MTX-mediated antiproliferative effects on endothelial cells (3C) and B cells (BT) contributing to the pattern of TCZ activities.

**Conclusion:** These data show that though TCZ has diverse effects on inflammatory responses, cotreatment with MTX elicits few additional activities and does not impact TCZ effects. In contrast, TOF + MTX impacts immune function, inflammation markers, and matrix-remodeling end points in human primary cell disease models differently than does TOF or MTX alone. The pharmacodynamic interactions between TCZ and MTX in BioMAP are significantly less pronounced than those between TOF and MTX. These data are consistent with the comparable efficacy of TCZ, monotherapy, and combination therapy seen in some clinical trials and in real life and suggest that TOF could be more beneficial in combination with MTX.

IgG4-RD. All patients had biopsy-proven disease and 75 were on no immunosuppression at the time of evaluation yet had active disease. Clinical and laboratory data were extracted from the electronic medical record. An IgG4-RD responder index score > 3 defined active disease. Serum IgG4 concentrations were determined by nephelometry after serial dilution to prevent the prozone effect. Circulating plasmablasts and SLAMF7+ CD4+ T cells were measured by flow cytometry.

**Results:** The average ages at evaluation and disease onset were 55 years (range: 24–83) and 49.9 years (range: 12–82), respectively. The majority of patients were white (75%) and male (63%); the mean number of organs affected was 2.8 (range 1–7). The most commonly involved organs were the submandibular glands, orbit, lymph nodes, pancreas, and retroperitoneum; fifty-five patients had sustained permanent damage due to IgG4-RD (Table 1).

Forty-seven patients had received glucocorticoid therapy and all had had either failed treatment or required ongoing treatment to maintain disease control. Only 38 (53%) of the 75 patients on no treatment at baseline had an elevated serum IgG4 concentration. Elevated serum IgG4 levels correlated with an inflammatory phenotype (increased acute phase reactants) and multi-organ disease. Regardless of the serum IgG4 concentrations, patients had elevated levels of circulating SLAMF7+ CD4+ T cells and plasmablasts. Male patients had a higher average serum IgG4 concentration (597 mg/dL versus 233 mg/dL; P = 0.03) but neither the proportion with an elevated baseline value nor the number of organs involved differed. Patients with renal disease, lymphadenopathy, and retroperitoneal fibrosis represented distinctive subtypes on the basis of complement levels, serum IgG4 concentrations, number of organs involved, and inflammatory markers.

**Conclusion:** We report the baseline features of our first 100 patients with biopsy-proven IgG4-RD. The majority of the patients were on no treatment at the initial assessment, permitting insights into the pre-treatment features of IgG4-RD. Our study stands in contrast to all IgG4-RD publications to date as this is the first study to describe the clinical and laboratory features of a large, diverse cohort with IgG4-RD.

Characteristic Phenotype of Peripheral Blood Lymphocytes in Patients with IgG4-Related Disease, Comparing to Primary Sjögren Syndrome and Healthy Controls. Shintaro Hirata, Shingo Nakayamada, Satoshi Kubo, Makio Yoshiyukawa, Naoki Yoneue, Kazuhisa Nakano, Kunihiro Yamaoka, Kazuyoshi Saito and Yoshika Tanaka. University of Occupational and Environmental Health, Japan; Kitakyushu, Japan.

**Background/Purpose:** IgG4-related disease (IgG4-RD) is a systemic disease that is characterized by the infiltration of IgG4-positive plasma cells and T cells into various organs. However, the characteristic and pathological role of immune cell subsets remains unclear. We have characterized peripheral blood immune cell subsets in patients with IgG4-RD by comparing with patients with primary Sjögren syndrome (pSS) and healthy controls (HC).

**Methods:** PBMC Cs were obtained from 8 IgG4-RD and 4 pSS patients as well as from 8 HC. The phenotype of immune cells was analyzed by 8-color staining flow cytometry. T helper cells were categorized as naive, central memory, effector memory and effector T cells by expression of CCR7 and CD45RA. B cells were categorized as naive IgM memory, switched memory, B cell and plasmablast (PB) by expression of CD19, CD27 and CD38. DCs were categorized as myeloid and plasmacytid DC by expression of CD11c and CD123. The proportion of immune cell subsets was assessed with correlations with serological parameters, including serum IgG, IgG4, and CRP.

**Results:** Baseline characteristics of patients with IgG4-RD (mean ± SD) were: age 56 ± 20 year, symptom duration 16.3 ± 19.2 months, serum IgG4 628 ± 549 mg/dl, CRP 1.3 ± 2.6 mg/dl, respectively. There was no difference in the proportion of T helper cells (Th1, Th2, Th17, Treg), B cells or DC subsets between IgG4-RD, and pSS, HC. CD3+CD4+CXCR5+CD45RA-Th cells were significantly higher in IgG4-RD than HC (p = 0.033). In contrast, the proportion of CD3+CD4+CCR7-CD45RA+ effector T cells and CD19+CD27+CD20-CD38- plasmablasts significantly increased in IgG4-RD compared to pSS and HC (p values: 0.008 and 0.013, respectively). Importantly, the proportion of CD3+CD4+CCR7-CD45RA+ effector T helper cells was strongly correlated with the ratio of serum IgG4/IgG ratio (rho = 0.90, p = 0.002), whereas it was not with that of plasmablasts (rho = 0.17, p = 0.67).

**Conclusion:** These results revealed that the higher proportion of effector T cells including Th1 cells and the increase of plasmablasts possibly induced by Th1 are characteristically observed in IgG4-RD, but not in pSS. Moreover, serum IgG4/IgG ratio was strongly correlated with ratio of effector memory T cells, but not plasmablasts. Taken together, IgG4 overproduction may be conducted by matured effector phase helper T cells, suggesting a pivotal role of effector phase T cells in pathogenesis of IgG4-RD, especially in IgG4 specific production. Further studies are required to elucidate the detailed role of effector phase T cells in the pathogenesis of IgG4-RD.
Background/Purpose: Staphylococcus aureus is the most common cause of adult septic arthritis and the incidence of methicillin-resistant Staphylococcus aureus (MRSA) infections continues to rise. There is a relative lack of information on clinical presentations and outcomes in MRSA septic arthritis and how it differs from methicillin-sensitive Staphylococcus aureus (MSSA) septic arthritis. Our aim was to evaluate the differences in clinical features and outcomes between patients with MRSA and MSSA septic arthritis.

Methods: This is a retrospective chart review study performed at a tertiary-referral level hospital. We queried the electronic database for patients with a discharge diagnosis of pyogenic arthritis between Jan 1st 2000 and Dec 31st 2013. We only included native joint septic arthritis. We collected data on patient demographics, clinical information, and patient outcomes. Statistical analysis was performed using SPSS statistics 20.0. The institutional review board at Texas Tech University approved this study.

Results: We identified 274 patients with native joint septic arthritis. Staphylococcus aureus caused 122 cases. MRSA caused septic arthritis in 45 patients; MSSA caused septic arthritis in 77 patients. Patient characteristics, clinical features and outcomes of MRSA septic arthritis patients and MSSA septic arthritis patients are summarized in Table 1. MRSA and MSSA septic arthritis occurs predominantly in males. There were no differences between the two groups in mean age. MRSA septic arthritis patients had more comorbidities than MSSA septic arthritis patients. There were no statistically significant differences in the initial clinical presentation between both groups (fever, leukocytosis, presence of bacteremia, polyarticular involvement, mean WBC count on synovial analysis). Only 77.8% of MRSA patients were treated initially for MRSA. The MRSA septic arthritis patients had a higher mean number of joint surgeries and longer hospital lengths of stay. They also had worse patient and joint outcome and higher rates of development of osteomyelitis adjacent to the joint.

Conclusion: We recorded a significant number of MRSA septic arthritis cases from the year 2000 to 2013. MRSA septic arthritis affects patients with multiple comorbidities and is associated with worse outcomes. Only 77.8% of MRSA septic arthritis patients were treated empirically for MRSA on initial presentation. Since MRSA is an emerging clinical entity in septic arthritis, rheumatologists have to consider this pathogen in patients with septic arthritis and more research is needed to improve patient outcomes.

ACR Concurrent Abstract Session Rheumatoid Arthritis - Clinical Aspects V: Mortality and Other Outcomes Tuesday, November 18, 2014, 2:30 PM–4:00 PM

2810 Reduced Mortality Risk in Rheumatoid Arthritis: Findings from Two UK Inception Cohorts. Sam Norton1, Elena Nikolichporou1, Lewis Carpenter1, David Walsh2, Patrick Kielty2, Josh Dixey2 and A dam Y young2, 1King’s College London, London, United Kingdom, 2University of Hertfordshire, Hatfield, United Kingdom, 3University of Nottingham, Nottingham, United Kingdom, 4St. Georges Healthcare NHS Trust, London, United Kingdom, 5New Cross Hospital, Wolverhampton, United Kingdom, 6ERAS, St Albans City Hospital, St Albans, United Kingdom.

Background/Purpose: Rheumatoid arthritis (RA) is associated with a 20 to 30% increased risk of mortality from all-causes compared to the general population. The aim of the present study is to examine whether, as observed in the general population, mortality rates in RA have decreased over the past 25 years. Furthermore, to assess whether changes are due to a potentially milder disease at presentation or change in treatment practise.

Methods: Data from 32 centres in the UK that recruited 2763 patients to two inception cohorts between 1986 and 2012 were combined for the analysis: Early RA Study and Early RA Network. Both recruited DMARD naïve patients at presentation to the rheumatology clinic. Death certificates were provided by the NHS central register. All-cause mortality was standard against population rates (stratified by age, sex and calendar year) to examine whether excess mortality risk had changed over time. Pooled logistic survival models estimated the relative yearly reduction in mortality hazard. M arginal structural modelling was used to examine the effect on methotrexate on survival, adjusting for confounding by indication of the treatment effect.

Complications, in spite of a few case reports of HPV infection in chronic inflammatory arthritis and psoriasis under this therapy. Therefore, the purpose of our study was to evaluate HPV and CT infections in RA patients pre- and 6 months post-TNF blocker. The possible associations among these infections, demographic data, sexual function, disease parameters and treatment were also analyzed.

Methods: Fifty female RA patients (ACR criteria), who were eligible to anti-TNF therapy, (n=50 at baseline (BL) and n=45 after 6 months of treatment (M6)) and 50 age-matched healthy controls were prospectively enrolled. All RA patients and controls had previous sexual activity. Exclusion criteria were: current pregnancy, early post-partum period, diabetes mellitus, psychiatric diseases and cervical cancer. They were assessed for demographic data, gynecological, sexual, cervical cytology and histological evaluations, disease parameters and current treatment. HPV DNA and CT DNA testing in cervical specimens were done using Hybrid Capture II assays.

Results: At BL, the median current age of RA patients and controls was 49 (18–74) years vs. 49 (18–74) years, p=0.1. A trend of lower frequency of HPV infection was observed in AR patients pre anti-TNF compared to controls (14% vs. 30%, p=0.054). None of patients had genital warts. Further evaluation of AR patients with and without HPV infection before anti-TNF therapy showed that the former group had a higher frequency of sexual intercourse (100% vs. 48%, p=0.014), higher median number of sexual partners (11±1 vs. 0.001, p=0.032) and higher frequency of abnormal cervical cytology (45% vs. 7%, p=0.029). Current age, disease duration, physician and patient visual analogue scales, DAS 28, ESR, CRP and treatments were alike in both groups (p>0.05). At M6 after TNF blockade, HPV infection remained unchanged in five patients, whereas two became negative and one additional patient turn out to be positive (MCN'emar's test p=1.0). None of them had cervical cancer in Pap smear. CT infection was uniformly negative in RA patients pre- and post-TNF blockade and in controls.

Conclusion: To our knowledge, this was the first study to assess prospectively genital infections in RA patients under TNF blockage therapy. Anti-TNF does not seem to increase short-term risk or severity of HPV and CT infections in RA patients.
Results: The excess mortality risk in RA compared to the general population reduced over time. Restricting the analysis to deaths within 10 years of onset, for ERA5 (recruitment 1986 to 2001) the all-cause standardised mortality ratio (SMR) was significantly increased (1.21; 95%CI 1.10 to 1.34), whereas for ERAN (recruitment 2002 to 2012) it was non-significant (1.04; 95%CI 0.88 to 1.22). The difference between SMR’s for the two cohorts was non-significant. Combining the two cohorts, year of symptom onset was significantly associated with all-cause mortality risk (HR = 0.96, p<0.001; 95%CI 0.95 to 0.96). Controlling for demographic and clinical features at baseline did not reduce the magnitude of the effect for year of onset (HR = 0.95, p<0.001; 95%CI 0.93 to 0.97). Extending the model to control for treatment using a marginal structural modelling approach, the use of methotrexate (use of which increased dramatically over the period of recruitment) was associated with a 60% reduction in the risk of death (HR = 0.40, p<0.001; 95%CI 0.25 to 0.64). A trial controlling for methotrexate use to estimate the effect of year of onset was reduced to non-significant (Hazard ratio = 0.98, p<0.01; 95%CI 0.96 to 1.01).

Conclusion: Substantial gains in life expectancy have been observed for people with RA in the UK over the last 25 years. The excess mortality risk appears to have been greatly diminished. This is probably due to changes in treatment practice, rather than RA becoming milder at presentation.

2011

Background/Purpose: Rheumatoid Arthritis (RA) patients commonly report reductions in fatigue after commencing Anti-TNF therapy. The mechanisms behind such reductions have not been determined, although it is assumed that changes in disease activity drive improvements. Nevertheless, to promote improvement in this patient priority, the true pathways to change in fatigue must be elucidated. Using Structural Equation Modelling (SEM), this study aimed to be the first to determine the pathways to improvement in fatigue among RA patients commencing Anti-TNF therapy.

Methods: Participants recruited to a long-term cohort study (the British Society for Rheumatology Biologics Register for RA) provided information on fatigue (SF 36 Vitality), disease activity (DAS 28) and other putative mediators of fatigue change (including disability, pain and mental health) at Anti-TNF therapy commencement and 6 month follow-up. A SEM path model, using the data of 2652 participants with high baseline fatigue (SF 36 Vitality =12.5,), was constructed employing a model generation approach. The total, direct and indirect effects of each putative mediator on improvement in fatigue were quantified using path coefficients. Where indirect effects accounted for more than 50% of total effect, the variable was considered to be mediated by other variables in the model.

Results: Significant pathways to improvement in fatigue (Figure 1) were shown to originate from changes in disease activity, pain, mental health, and disability, as well as a history of depression and participant sex. The model accounted for 40% of the variance in change in fatigue and demonstrated a good model fit ($\chi^2$ = 0.18, df=3, p=0.98). The largest absolute improvements in fatigue were associated with a one standard deviation improvement in pain and mental health (0.31 and 0.28 unit improvement in fatigue, respectively). As 82% of the total effect of change in disease activity was indirect, the variable was mediated by other variables in the model. Specifically, 50% of the indirect effect was mediated through a change in pain and an additional 14% through pain and mental health improvement.

Conclusion: Improvement in RA related fatigue after commencing Anti-TNF therapy is driven by reductions in pain, rather than directly from disease activity. In addition, mental health and disability are important mediators in the pathway to fatigue improvement and should be targeted, in an attempt to further improve this patient priority.

1 Jyväskylä Central Hospital, Jyväskylä, Finland, 2 Jyväskylä Central Hospital, Jyväskylä, Finland, 3 Tampere University Hospital, Tampere, Finland, 4 Medcare Oy, Äänekoski, Finland, 5 Jyväskylä Central Hospital, Jyväskylä, Finland, 6 Kuopio University Hospital, Kuopio, Finland, 7 Jyväskylä Central Hospital, Jyväskylä, Finland.

Background/Purpose: Rheumatoid arthritis (RA) is suggested to be a more severe disease in women than in men as disease activity appears higher in women, and men meet remission criteria more often.

Long-term severity of RA can be analyzed from permanent joint damage in radiographs. Our purpose was to study possible differences in the extent of radiographic joint damage between women and men in an early RA cohort at 10 years after diagnosis.

Methods: Our early RA cohort includes 990 patients from a single clinical diagnosis with a clinical diagnosis of early RA in 1997 – 2004. Radiographs of hands and feet were taken at a 10 year follow-up visit after diagnosis and were analyzed according to the Larsen score (0–100) including MCP I–V, wrists, and MTP II–V.

Results: Baseline characteristics of 990 patients were: the mean (SD) age 57(16) years, 67% female, 61% seropositive (RF/CCP+) and median (IQR) duration of symptoms before diagnosis 6(3, 12) months; 657(66%) patients were available for a 10 year follow up. Reasons for non-attendance among 333 patients included death (52%), high age, multi-comorbidity or institutionalization (10%), moving from the area (12%); 8% declined, 4% were lost to follow-up and 14% miscellaneous reasons. Thus, radiographs were available in 462 women and 195 men with a similar percentage of 66% being seropositive among genders. In seropositive patients, the mean (SD) Larsen score was 7.1(10) in women and 8.1(11) in men, p=0.12. The probability plot was similar for women and men (Figure 1). In seronegative patients, the mean (SD) Larsen score was 1.9(3.8) in women and 2.3(4.5) in men, p=0.29.

Conclusion: At 10 years after diagnosis, RA joint damage appears similar in both genders. RA severity is comparable between women and men.

Figure. Larsen score in seropositive women and men with early RA at 10 years after diagnosis.

Tuesday, November 18

Background/Purpose: Morning stiffness may not be specifically queried by rheumatologists in the course of their regular interactions with rheumatoid arthritis (RA) patients. This analysis investigated whether morning stiffness was correlated with measures of disease activity.

Methods: Data from the Corrona RA Registry included RA patients who initiated a new therapy: non-biologic or biologic DMARD, whether as mono-therapy or in combination, and remained on treatment for >90 days. Patients were evaluated at initiation, 1 and 2 years after initiation and time of last visit. Correlations of measures of disease activity with presence and change in morning stiffness were modeled at the patients' last Corrona visit between January 2013 and February 2014. For patients with >= one visit during this interval, propensity score (PS) trimming of the top and bottom 5% was used to obtain comparable populations with and without morning stiffness. Thus data from 90% of RA patients (5379 subjects) were utilized to examine the association of measures of disease activity: remission (CDAI <2.8); low disease activity (2.8 < CDAI < 10); moderate disease activity (10 < CDAI < 22) and high disease activity (CDAI ≥ 22) with presence/absence of morning stiffness, after PS trimming at time of last visit.

Results: At baseline those with morning stiffness (n=9688) were less likely to be working, more likely to have received biologic therapy, Medicaid insurance, and to have higher measures of disease activity than those without (n=2865): CDAI high: 34.1 vs 10.3%; remission/low: 31.6 vs 66.3%, p<0.0001. At one year after initiation of treatment, these differences persisted (with morning stiffness (n=6140) without (n=2957), including statistically significantly higher mHAQ scores: 0.5 ± 0.5 vs 0.1 ± 0.3, p<0.0001; more reporting disabled work status: 21.7 ± 5.2%, p<0.0001 and CDAI high: 21.7 ± 5.2%; remission/low: 48.0 ± 80.2%, p<0.0001. These differences persisted even after 2 years of follow-up (with morning stiffness (n=4466) without (n=1895): mHAQ scores unchanged; disabled: 29.2 vs 9.4%; CDAI high:19.3 ± 3.9% remission/low: 51.4 ± 82.0, all p<0.0001. At time of last Corrona visit, higher CDAI, mHAQ and patient reported fatigue were significantly associated with presence of morning stiffness and increased persistence of morning stiffness (Figure 1).

Conclusion: In this registry analysis, presence and persistence of morning stiffness consistently reflected higher disease activity associated with more impairment of physical function and self reported work disability.

Time-to-Remission, Time-to-Relapse and Disease Severity at the Time of Relapse in RA - Results from the Ontario Best Practices Research Initiative (OBR1). Bindee Kuriya, Xuying Li, Binu Jacob, Pooneh Akhavan, Jessica Widdifield, Mark Tabangilo, Janet E. Pope, Edward Hadjiiski, Corrinne Dunn, Claire Bombardier, H. University of Toronto, Toronto, ON, 2University Health Network, Toronto General Research Institute, Toronto, ON, 3Early Rheumatoid Arthritis Program, Mount Sinai Hospital and University of Toronto, Toronto, ON, 4Western University, London, ON, 5Mount Sinai Hospital, University of Toronto, ON, 6Institute for Work & Health, Toronto, ON.

Background/Purpose: Clinical remission in RA is the desired goal, however the ability to sustain remission and the timing and severity of relapse is not well known. We aimed to describe time to remission, time-to-relapse and disease activity at the time of relapse.

Methods: We performed a longitudinal data analysis of patients enrolled in the Ontario Best Practices Research Initiative (OBR1), a clinical registry of RA patients followed in routine care. The prevalence of a first occurrence of clinical remission according to the DA28-ESR < 2.6 or CDAI << 2.8 following cohort entry (baseline) was determined as was the average time-to-remission. Patients achieving remission with >=1 follow-up visit (typically spaced 3 to 6 months apart) were observed for the average time until relapse, defined as a DA28 > 2.6 or CDAI > 2.8. The baseline disease activity level of those achieving remission and the disease activity level at the time of relapse was examined.

Results: The total cohort (N=2305) was 78% female with mean (SD) age 57 (17) years, disease duration 8.6 (9.6) years and mean DAS28 score 4.5 (1.5) at baseline. Remission was achieved in 1081 patients (47%): 140 of these patients had low baseline disease activity, 516 had moderate and 369 had high disease activity at baseline. The median time to remission was 279 days (interquartile range [IQR] 146 - 482) and remission was reached significantly faster among those starting with low disease activity (median 216 days, IQR 148-355) at baseline compared to more severe disease (median 357 days, IQR 173-563) (P<0.001). Nineteen hundred eighteen patients (85%) had continued follow up after remission and 582 (59%) went on to experience a relapse. The median time-to-relapse was 197 days (IQR 126-363). The majority switched from a state of remission to mild or moderate disease activity, in contrast to the moderate to severe levels of disease activity they experienced at baseline (Table). Hence the ability to sustain remission and the timing and severity of relapse is not well known. We aimed to describe time to remission, time-to-relapse and disease activity at the time of relapse.

Table. Disease activity according to DAS28 or CDAI at time of relapse according to baseline level disease activity.

Better Functional Ability with Less Biologicals 2 years after Induction with Combination DMARD Therapy versus methotrexate Monotherapy. T. Martinuliu, J. J. Luime, P. H. P. de Jong, A. H. Gerards, D. van Zeven, I. Tchetverikov, P. B. J. de Sonnaville, M. van Kruigen, B. Grilliet, J. M. W. Hazez and A. E. A. Wael, 2 Erasmus University Medical Center,
Background/Purpose: To assess differences in frequency of biological therapy use and functional ability in early RA patients two years after starting induction therapy according to three different treatment regimens.

Methods: Data were used from patients with recent-onset arthritis participating in a single-blinded clinical trial (Treatment in the Rotterdam Early Arthritis Cohort (tREACH)) in which three induction therapy strategies were compared: (A1) combination therapy (methotrexate (MTX) + sulfasalazine + hydroxychloroquine) with glucocorticoids (GCs) intramuscularly; (A2) combination therapy with an oral GC tapering scheme and (B) MTX with oral GCs similar to B. As no difference in disease activity scores (DAS) was found between groups A1 and A2 at 3 and 12 months of follow-up (1), these groups were combined for this analysis (group A). Disease activity scores (original DAS) were assessed every 3 months. Functional ability was assessed using the Health assessment questionnaire (HAQ). Data were analysed using simple descriptive statistical techniques.

Results: 281 patients (91 men, 190 women; mean baseline DAS 3.3, median baseline HAQ 1.00) were initially randomized. Data on medication use at 2 years were available from 248 patients (88%), see figure 1. A1, A2 years, 24% of patients in group A versus 43% in group B were using a biological DMARD. Biological use and DAS over time are demonstrated in figure 2.

Equal mean DAS of 1.66 (95% CI 1.54–1.78) at 24 months was observed for the initial treatment groups at 24 months (group A: 1.58 (95% CI 1.43–1.73), group B: 1.80 (95% CI 1.58–2.02). DAS remission (DAS<1.6) was achieved by 55% of patients.

The median disability score (HAQ (min-max)) was 0.38 (0–2) for all patients but varied in the treatment groups: A. 0.25 (0–1.9) and B. 0.63 (0–2.1) (p=0.042).

Conclusion: We observed lower use of biological therapy and better functional ability in induction triple therapy compared to induction monotherapy MTX with GC bridging at 2 years of follow-up in the treat-to-target tREACH study. No differences were found for disease activity scores.

Histone Deacetylase One Contributes to the Auto-Aggressive Phenotype of Rheumatoid Arthritis. Sarah Hawtree1, Munita Muthana2, J. Mark Wilkinson3, Athony G. Wilson3 and M ohammed Akil4. 1University of Sheffield, Sheffield, United Kingdom, 2Rheumatology Department, Sheffield South Yorkshire, United Kingdom.

Background/Purpose: Rheumatoid arthritis (RA) is a chronic, autoimmune, inflammatory disease that affects synovial joints. A key characteristic of RA is hyperplasia of fibroblast-like synoviocytes (FLS) which develop a stable, auto-aggressive phenotype that augments tissue destruction. It is unknown how this phenotype is stably maintained, however epigenetic changes have been implicated. Histone acetylation is a major epigenetic mechanism (HDACs). The objective of the study is to determine the role of histone deacetylases (HDACs) in regulating the auto-aggressive phenotype of RA FLS.

Methods: Real-time qPCR was used to compare levels of HDAC1-11 in RA compared with osteoarthritis (OA) FLS. Joint biopsies were co-stained with anti-HDAC1 and anti-fibroblast antibodies. HDAC1 and a non-targeting control (NTC) siRNA were transfected in vitro into RA FLS. Cell proliferation, migration and invasion after siRNA knockdown (KD) were assessed by using tritiated thymidine, a scratch assay and a matrigel invasion assay respectively. An Illumina BeadChip (47,000 transcripts) was used to analyse global gene expression changes after KD. The in vivo effect of HDAC1 KD was investigated in a mouse model of collagen-induced arthritis (CIA) using in vivosRNA. Clinical scores of CIA were measured daily (days 0–49) and the bones were analysed using a microCT scanner.

Results: The mRNA levels of HDACs 1–11 are higher in RA compared to OA FLS, with HDAC1 levels showing a 4.2-fold increase (p = 0.03, n = 7–10). HDAC1 KD reduced FLS proliferation (p = 0.04, n = 6), migration (p = 0.01, n = 6) and invasion (p = 0.02, n = 6) compared to the NTC. Cluster analysis of the microarrays (n = 3) revealed significant changes in genes involved in apoptosis (p = 0.009, n = 21), migration (p = 0.008, n = 4) and proliferation (p = 0.009, n = 9). In mice with CIA, HDAC1 KD significantly inhibited joint inflammation (p = 0.001, n = 10) and reduced bone erosion compared to the NTC.

Conclusions: Our data implicates HDAC1 in controlling the autoaggressive phenotype of FLS in RA and our data in murine inflammatory arthritis supports targeting HDAC1 as a potential therapy in RA.

SH2 Domain-Containing Phosphatase 2 Promotes Aggressiveness of Rheumatoid Fibroblast-like Synoviocytes. Stephanie M. Stanford1, Gerrman R. Aleman Muench1, Cristianos Pasciuti, Liqian Zeng2, David L. Boyle3, Gen-Sheng Feng1, Zhong-Yin Zhang1, Maripat Corr2, Gary S. Firestein3 and Nunzio Bartok4. 1La Jolla Institute for Allergy and Immunology, La Jolla, CA, 2Indiana University School of Medicine, Indianapolis, IN, 3University of California at San Diego School of Medicine, La Jolla, CA, 4University of California at San Diego Division of Biological Sciences, La Jolla, CA.

Background/Purpose: In rheumatoid arthritis (RA), fibroblast-like synoviocytes (FLS) that line joint synovial membranes aggressively invade the extracellular matrix, destroying cartilage and bone. Although this cell type mediates RA pathogenesis, it is currently untapped as a drug target. Signal transduction in FLS is mediated through multiple pathways involving protein tyrosine phosphorylation, and thus we sought to identify the protein tyrosine phosphatases (PTPs) regulating the aggressiveness of FLS from RA patients (RA FLS). We previously profiled the expression of all PTPs in FLS from RA and osteoarthritic (OA) patients, and found that the PTPN11 gene, encoding the PTP SHP-2, is upregulated in RA FLS. We previously demonstrated that SHP-2 enzymatic activity is mediated through multiple pathways involving protein tyrosine phosphorylation, and thus we sought to further explore the role of SHP-2 in mediating pathogenesis of RA.

Methods: Inhibition of SHP-2 enzymatic activity was achieved using a specific SHP-2 chemical inhibitor (Median [IQR] % maximum activity inhibition: 79 [51–95] for vehicle-treated mice and 90 [75–99] for inhibitor-treated mice; p < 0.0001 by two-way ANOVA test of 14-day arthritis course). Global inhibition of SHP-2 activity by daily administration of 7.5 mg/kg SHP-2 inhibitor also led to reduced arthritis severity (Median [IQR] change in ankle thickness after 8 days: 3.62 [3.08–3.78] for Cre−/− mice and 0.46 [0.11–1.69] for Cre+ mice; p < 0.0001 by two-way ANOVA test for 14-day arthritis course).

Conclusions: These data indicate that SHP-2 promotes the aggressiveness of RA FLS, a role that is dependent on the catalytic activity of the phosphatase. Both global inhibition and inducible deletion of SHP-2 in hematopoietic cells caused a reduction in arthritis severity, suggesting SHP-2 could be a potential target for therapy in RA.

The YAP Pathway Regulates Fibroblast-like Synoviocyte Invasion. Beatrice Bartok. University of California, San Diego, La Jolla, CA.

Background/Purpose: Fibroblast-like synoviocytes (FLS) in RA possess unique transformed phenotype, such as cartilage invasion that is maintained independent of cytokines and other inflammatory cells. However, the molecular mechanisms that regulate FLS behavior in RA are poorly understood. The transcriptional coactivator YAP is associated protein (YAP) was recently shown that is dysregulated in RA compared with OA FLS. Increased YAP activity might contribute to persistent activation and pathogenic behavior of RA FLS. Therefore, we assessed role of YAP in synoviocyte invasion.

Methods: We used siRNA knock down and chemical inhibition to assess effect of YAP activation on RA FLS invasion. We used Verteporfin to inhibit YAP transcriptional activity. For siRNA knockdown, YAP and control siRNA were transfected using AMAXA technology. FLS invasion was studied using M atrigel coated transwells, 3 days following transfection. YAP inhibitor or vehicle was added to the upper chamber and PDGF was used as chemoattractant in the lower chamber. The cytoskeleton and focal adhesions were visualized and confocal microscopy using rhodamin phalloidin and anti-Vinculin staining. M MP expression was measured using qPCR.

Results: The YAP inhibitor Verteporfin significantly decreased number of invading cells in a concentration dependent manner, with 65–5% inhibition at 0.1 μM (p < 0.02, n = 3). Similar results were obtained when YAP was knocked by siRNA. Cells with reduced YAP activity displayed 52–6% (p = 0.04, n = 3) decrease in invasion through M atrigel matrix compared with scramble control. To determine effect of YAP knockdown on cell adhesion and migration in a three dimensional matrix, cells were stained with phalloidin and anti-Vinculin. RA FLS treated with the YAP inhibitor Verteporfin displayed diminished stress fiber formation and decrease in focal adhesion formation by 56–5% (p < 0.04, n = 3) visualized with confocal microscopy. Similar findings were obtained when YAP was inactivated by siRNA knock down. To determine the effect on M MP production cells were stimulated with TNF and qPCR was performed for MMP1, 2, 3, 9 and 11. MMP1 and MMP3 were significantly lower in YAP deficient cells compared with scramble control (p < 0.03 and p < 0.05, n = 3), while MMP2,9 and MT1MMP mRNA were unchanged. Similar findings were obtained using chemical inhibition with Verteporfin.

Conclusions: The YAP pathway is a major regulator of FLS invasion by modulating focal adhesion formation and M MP production. These observations, together with our previous findings that increased YAP activity in RA FLS compared with OA suggest that YAP activity might contribute to persistent activation and pathogenic behavior of RA FLS. Therefore, modulating YAP pathway might represent a novel therapeutic approach for RA.

Dual Role for B Cells in Promoting Bone Erosion in Rheumatoid Arthritis Via Effects on Osteoclast and Osteoblast Differentiation. Nida Meednu, Hengwei Zhang, Teresa Owen, Liangping Xing and Jennifer H. Arolnik. University of Rochester, Rochester, NY.

Background/Purpose: In the K/BxN mouse arthritis model, we found that inducible deletion of SHP-2 in hematopoietic cells led to >50% reduction in arthritis severity (M edian [IQR] change in ankle thickness after 8 days: 3.62 [3.08–3.78] for Cre−/− mice and 0.46 [0.11–1.69] for Cre+ mice; p < 0.0001 by two-way ANOVA test for 14-day arthritis course). Global inhibition of SHP-2 activity by daily administration of 7.5 mg/kg SHP-2 inhibitor also led to reduced arthritis severity (M edian [IQR] change in ankle thickness after 8 days: 2.65 [1.81–3.27] for vehicle-treated mice and 2.14 [0.70–2.73] for inhibitor-treated mice; p < 0.01 by two-way ANOVA test for 14-day arthritis course).

Conclusions: These data indicate that SHP-2 promotes the aggressiveness of RA FLS, a role that is dependent on the catalytic activity of the phosphatase. Both global inhibition and inducible deletion of SHP-2 in hematopoietic cells caused a reduction in arthritis severity, suggesting SHP-2 could be a potential target for therapy in RA.

2820
Background/Purpose: Rheumatoid arthritis (RA) is a systemic autoimmune disease that often leads to joint damage, a process mediated by an imbalance between bone resorption and bone formation. Additional evidence implicates the role of B cells in joint destruction including the presence of B cell aggregates in RA synovium and subchondral bone and the efficacy of B cell depletion therapy in halting radiographic progression. However, B cell effects on bone have been described as mediated via indirect influences on other immune cell such as T cells. Whether B cells directly affect bone homeostasis in RA is not known. In this study we investigated the effects of B cells on osteoclast (OC) and osteoblast (OB) functions in RA.

Methods: Isolated B cells from peripheral blood of healthy controls (HC) or RA patients were stimulated with α-CD40 and PMA for 96 h, and RANKL and TNF production was assessed by flow cytometry, ELISA, and qPCR. Stimulated and un-stimulated B cells were fixed then co-cultured with hMSCs (Lonza, #PT-2501) for 24 h and the expression of OB transcription factor RUNX2 and Notch signaling molecules, Hes1 and Hey1 in hMSCs was detected by qPCR.

Results: B cells stimulated with α-CD40 and PMA produce significant amounts of RANKL as compared to un-stimulated B cells (%RANKL: 4.9 ± 0.94 vs. 0.413 ± 0.005, P < 0.0001). Stimulated RA B cells induced significantly more OC formation in comparison to HCs B cells (using the same donor for OCP) (%OC/Well: RA: 60.5 ± 7.5 vs. HC: 12 ± 7, P < 0.0001). Notably, stimulated RA B cells expressed higher RANKL than memory B cells from HC (%RANKL: 20.4 ± 1.68 vs. 11.25 ± 3.15, P < 0.05). In parallel, RA memory B cells expressed higher RANKL than memory B cells from HC (%RANKL: 10.3 ± 0.9 vs. 7.4 ± 0.5, P < 0.05). RA CD45- MSC-enriched cells isolated from peripheral blood have reduced expression of Hes1 and Hey1. In agreement with this finding, RA CD45- MSC-enriched cells significantly increased levels of Hes1 and Hey1. RA CD45- MSC-enriched cells significantly increased levels of Hes1 and Hey1. In agreement with this finding, RA CD45- MSC-enriched cells significantly increased levels of Hes1 and Hey1.

Conclusion: Our finding suggest that B cells play a critical role in promoting bone erosion in RA both by directly enhancing osteoclastogenesis and inhibiting osteoblast differentiation.

Disclosure: N. Meednu, None; H. Zhang, None; T. Owen, None; L. Xing, None; J. H. Anolik, None.
Conclusion: This second Phase 2 study demonstrates the potential benefit of inhibiting macrophage activity via the GM-CSF-R pathway on RA disease activity. The study met both co-primary endpoints with a clear dose response effect. An acceptable tolerability profile was demonstrated over the 24-week study period.

2822

Safety and Efficacy of Baricitinib through 128 Weeks in an Open-Label, Long-Term Extension Study in Patients with Rheumatoid Arthritis

Edward C. Keystone1, Peter C. Taylor2, Mark C Genovese3, Douglas E. Schlichting4, Inmaculada De La Torre5, Scott D. Beatte6 and Terence Rooney6. 1Mount Sinai Hospital, Toronto, ON, 2University of Oxford, Oxford, United Kingdom, 3Stanford University Medical Center, Palo Alto, CA, 4Eli Lilly and Company, Indianapolis, IN, 5Eli Lilly and Company, Alcobendas, Spain.

Background/Purpose: Baricitinib is an oral inhibitor of JAK1/JAK2 being investigated as a treatment for rheumatoid arthritis (RA). In a phase 2b study, baricitinib treatment resulted in significant clinical improvements over 24 wks1. The safety and efficacy findings of baricitinib treatment in RA patients (pts) up to 128 wks are reported here.

Methods: Pts were randomized to placebo (PBO) or 1, 2, 4, or 8 mg baricitinib QD for 12 wks (Part A). Pts assigned to 2, 4, or 8 mg continued assigned treatment and pts assigned to PBO or 1 mg were reassigned to 4 mg QD or 2 mg BID for an additional 12 wks of blinded treatment (Part B). Pts completing Part B were eligible to enter a 52 wk open-label extension (OLE: Wks 76–128, Part C), where pts in the 8 mg group continued to receive 8 mg QD and all other pts received 4 mg QD. During Part C, doses could be escalated to 8 mg QD at 28 or 32 wks at the investigator’s discretion when DAS 28 (CRP) > 4.4 and >=6 swollen joints were present. Pts completing Part C were eligible to enter an additional 52 wk OLE (Wks 76–128, Part D) where pts received 4 mg QD regardless of previous dose.

Results: Of 204 pts at sites participating in Part C, 201 (99%) were treated and 169 (84%) completed 52 wks. Among pts who remained on 4 mg (N = 108) in Part C, TEAEs occurred in 63%, SAEs in 16%, infections in 35%, and serious infections in 5%. A mong pts who received 8 mg at any time (N = 93) in Part C, TEAEs occurred in 68%, SAEs in 13%, infections in 40%, and serious infections in 3%. Of 150 pts at sites participating in Part D, 144 (96%) were treated and 133 (92%) completed an additional 52 wks. Among pts who remained on 4 mg (N = 79) in Part D, TEAEs occurred in 53%, SAEs in 6%, infections in 32%, and serious infections in 3%. Among pts who decreased to 4 mg (N = 65) in Part D, TEAEs occurred in 55%, SAEs in 6%, infections in 28%, and serious infections in 3%. The exposure-adjusted incidence rates for adverse events for all baricitinib groups in Part D were similar to or lower than those rates observed in Part C (Table 1). No opportunistic infections, tuberculosis cases, or lymphomas were observed through 128 wks. One death due to myocardial infarction occurred in the 8 mg group in Part C. Among all pts combined, the proportions of pts achieving ACR20 or disease improvement at Wk 24 were similar or improved at Wks 76 and 128 (Table 2).

Conclusion: Among pts completing 128 wks of a phase 2b study, clinical improvements observed at Wk 24 were maintained or improved through Wk 128. In addition, safety data collected during the OLE were consistent with previous baricitinib findings.

Comparative Efficacy of Sarilumab Plus Methotrexate in Biologic-Experienced and Biologic-Naive Patients with Moderate-to-Severe Rheumatoid Arthritis from a Phase 3, Randomized, Double-Blind, Placebo-Controlled, International Study

Roy Fleischmann1, Dennis L. Decktor2, Chunpeng Fan3, Hubert Van Hoogstraten4 and Mark C Genovese5. 1Metroplex Clinical Research Center and University of Texas Southwestern Medical Center, Dallas, TX, 2Regeneron Pharmaceuticals, Inc., Tarrytown, NY, 3Sanofi, Bridgewater, NJ, 4Stanford University Medical Center, Palo Alto, CA.

Background/Purpose: For patients with prior exposure to tumor necrosis factor-α inhibitor (TNF-I), the likelihood of response to subsequent treatment with a TNF-I declines with the increasing number of previous treatment failures.1 Sarilumab, a fully human monoclonal antibody directed against interleukin-6R, has shown efficacy in a study of adult rheumatoid arthritis (RA) patients with moderate-to-severe disease and an inadequate response to methotrexate (MTX).2 Sarilumab’s safety and efficacy has been demonstrated at subcutaneous doses of 150 mg or 200 mg q2w + MTX. A further analysis of the clinical efficacy and safety of sarilumab in patients with/without prior biologic use (physician-reported) from this study is reported here. In the total population, 21.2% were exposed to biologics, of which 50% had received prior TNF-I.

Methods: This was a subanalysis of the ACR20 (primary efficacy endpoint) and ACR50 and ACR70 responses, reduction of DAS28-CRP, and CDAI scores in patients with/without prior biologic use in the intention-to-treat population of the Phase 3 aspect of the MOBILITY study. Patients previously nonresponsive to biologic treatment were excluded from study participation.

Results: Both doses of sarilumab resulted in a statistically significant ACR20 response at Wk 24 vs placebo (p<0.0001); ACR50 and ACR70 responses were also statistically significant at Wk 24 (Fig 1). Statistically significant improvements in DAS28-CRP reduction were observed, with mean reductions at Wk 52 of −1.85, −2.80, and −3.15 in the placebo, sarilumab 150 mg, and 200 mg q2w groups, respectively, in patients with prior use of biologics, and −1.95, −3.24, and −3.29 in biologic-naive patients (Fig 2). Similar improvements were seen in CDAI scores, with mean reductions at Wk 52 of −23.23, −28.45, and −28.81 in the placebo, sarilumab 150 mg, and 200 mg q2w groups, respectively, in patients with prior use of biologics, and −24.52, −31.35, and −30.33 in biologic-naive patients (Fig 2).

Most common TEAEs included infections and injection site reactions. A higher incidence of serious infections was observed with sarilumab. Lab
abnormalities included decreases in neutrophils and increases in transaminases and lipids.

**Conclusion:** Independent of prior use of a biologic, treatment with sarilumab resulted in clinically meaningful and statistically significant responses; given the modest number of biologic-experienced participants and the exclusion of prior non-responders, additional research is warranted.

**2824**

A Profile of the Efficacy of Sarilumab Plus Methotrexate in Rheumatoid Arthritis Patients: Results of a 52-Week, Phase 3, Randomized, Double-Blind, Placebo-Controlled, International Study. Arthur Kavanaugh, Dennis L. Decktor, Chunpeng Fan, Janet van Aldenburg, Renata M. Arntsvora and Mark C. Genovese; 1University of California San Diego, La Jolla, CA, 2Regeneron Pharmaceuticals, Inc., Tarrytown, NY, 3Sanofi, Bridgewater, NJ, 5Sanofi Czech Republic, Prague, Czech Republic, 3Stanford University Medical Center, Palo Alto, CA.

**Background/Purpose** Interleukin-6 (IL-6) regulates a diverse array of activities that may underlie systemic and local symptoms of rheumatoid arthritis (RA). The efficacy of sarilumab, a fully human monoclonal antibody (mAb) directed against IL-6R, has recently been investigated in the randomized, double-blind, placebo(pbo)-controlled, multicenter, phase 3 part of the MOBILITY study. This analysis expands the profile to the entire 52-week duration of the trial.

**Methods:** Adults with active, moderate-to-severe RA and inadequate response to methotrexate (MTX) were randomized 1:1:1 to pbo + MTX, sarilumab 150 mg or 200 mg q2w + MTX for 52 wks. 3 co-primary endpoints associated with RA activity (signs & symptoms, physical function, and structural damage) were investigated: proportion of patients achieving ACR20 response at Wk 24; change from baseline in HAQ-DI at Wk 16; and change from baseline in mTSS at Wk 52. Secondary efficacy endpoints included major clinical response at Wk 52, ACR50 and ACR70 responses, reduction in DAS28-CRP, and CDAI.

**Results:** Sarilumab 150 mg and 200 mg q2w + MTX provided statistically significant, clinically meaningful improvement in all co-primary efficacy endpoints (ACR20, HAQ-DI, and mTSS) and secondary efficacy endpoints vs pbo + MTX (Table). ACR 20 response rates increased by Wk 2 and remained significantly higher in both sarilumab + MTX groups vs pbo + MTX through Wk 52 (p<0.0001). Change from baseline in the ACR core set of disease activity measures, swollen and tender joint counts, was significantly higher in the sarilumab + MTX groups vs pbo + MTX (Table). A significantly higher proportion of patients in the sarilumab + MTX groups maintained CDAI remission vs pbo + MTX (Wks 4-52; p<0.0001). DAS28-CRP scores were significantly improved vs pbo + MTX at Wks 2–52 (p<0.0001) in sarilumab + MTX–treated patients, who achieved DAS28-CRP remission at Wks 24 and 52 (Table). The proportion of HAQ-DI responders at Wks 16, 24 and 52 was significantly higher (p<0.0001) with sarilumab + MTX vs pbo + MTX at each timepoint (Table). Mean change from baseline in mTSS at Wk 52 with sarilumab + MTX was significantly higher vs pbo + MTX (Table). Most common TEAEs included infections and injection site reactions. A higher incidence of serious infections was observed with sarilumab. Lab abnormalities included decreases in neutrophils and increases in transaminases and lipids.

**Conclusion:** These additional analyses of patients with active RA and an inadequate response to MTX showed that treatment with subcutaneous sarilumab at 150 mg and 200 mg q2w + MTX improved the full range of reported outcomes in a robust and durable manner that was maintained over this 52-week trial.

1Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea; 2Eju National University, Jeju, Korea, South Korea; 3Catholic University of Daegu School of Medicine, Daegu, South Korea; 4Inha University Hospital, Incheon, South Korea; 5Hanwha Chemical, Seoul, South Korea; 6Hanwha Chemical, Daejeon, South Korea.

Background/Purpose: Etanercept is a recombinant fusion protein that blocks TNF activity. HD203 is a biosimilar of etanercept. In a double-blind, randomized study in healthy volunteers, HD203 and a reference etanercept were comparable with regards to pharmacokinetics, safety and tolerability. The aim of this study was to evaluate the equivalence in efficacy and to compare the safety of HD203 (biosimilar etanercept) and a reference etanercept, in combination with MTX in patients with RA. (ClinicalTrials.gov identifier NCT01270997).

Methods: Patients (male or female aged ≥20 years) with active RA were randomly assigned (1:1) to 25 mg HD203 or reference etanercept, administered subcutaneously twice weekly with MTX for 48 weeks. The primary endpoint was the proportion of patients achieving ACR20 at week 24. Secondary endpoints included ACRn, change in DAS28, and EULAR response at week 24 and 48, safety and immunogenicity. Efficacy and safety were evaluated at screening, week 0, 2, 4, 8, 12, 16, 20, and 24. Immunogenicity, efficacy and safety were also evaluated at week 36 and 48.

Results: In total, 294 patients were randomized: 147 to HD203 and 147 to reference etanercept, administered subcutaneously twice weekly with MTX for 48 weeks. The primary endpoint was the proportion of patients achieving ACR20 at week 24. Secondary endpoints included ACRn, change in DAS28, and EULAR response at week 24 and 48. ACR20 was achieved in 25% (95% CI 21.9 to 28.6) of patients receiving HD203 and 24% (95% CI 20.7 to 27.4) of patients receiving the reference etanercept. ACR20 at week 48 was higher with HD203 than with reference etanercept. There were no statistically significant differences between the groups for ACRn, change in DAS28, and EULAR response at week 24 and 48.

Table: Proportion of patients achieving ACR20 at week 24 and week 48

CI: confidence interval; PPS, per-protocol set; FAS, full analysis set; *Pearson’s chi-square test

A randomised, double-blind, placebo-controlled study, pts 18 years or older who met ACR criteria for RA, were not on concomitant MTX, and had active RA (defined as either CRP [***: possibility of New Font being added] >0.8 mg/dL or ESR [***: possibility of New Font being added] ≥28 mm/hr and [***: possibility of New Font being added] ≥10 tender and swollen joints) were randomized 1:1:1:1 to ASP015K 25 mg, 50 mg, 100 mg, 150 mg or PBO. Allowing concomitant DMARD therapies were anti-malarials and/or sulfasalazine. The primary endpoint was ACR20 response at week 12. Results: 289 pts (62% female mean age 53.9 years) were randomized and dosed. Approximately half the subjects (48%) were enrolled in the U.S. and the remainder from Europe (41%) and Mexico (11%). 48% had used a biologic, with 36% exposed to ≥ 2. Mean baseline values: disease duration, 10.4 y, tender joint count 25.7 (of 68), swollen joint count 16.3 (of 66), CRP 1.69 mg/dL, ESR 44.36 mm/hr, DAS28-CRP 3.83, and DAS28-ESR 6.64. A statistically significant difference was observed at week 12 when comparing ASP015K 100 mg and 150 mg with PBO. ACR50/70 responses in the two highest dose groups as early as week 4 were observed. ACR50/70 response at week 12 and DAS28-CRP remission were also higher in the 2 highest ASP015K dose groups as compared to PBO. Dose-dependent improvement in DAS28-CRP was seen, with statistically significant differences shown in the two highest dose groups as early as week 4. The incidence of adverse events (AEs) was similar between combined ASP015K groups and PBO (41.6% vs 43.1%). The most frequently reported AEs in the combined ASP015K groups as compared to PBO were upper respiratory tract infection (5.5% vs 3.9%), nausea (5.0% vs 0%), and diabetes (3.8% vs 2.0%). The overall incidence of infections and serious adverse events was similar between ASP015K and PBO (13.4% vs 13.7% and 4.2% vs 3.9%, respectively). No meaningful differences in absolute neutrophil and lymphocyte counts or hemoglobin were seen between ASP015K and PBO. The safety profile was generally comparable among the ASP015K dose groups, except for a higher incidence of dyspepsia, headache, and blood creatinine phosphokinase increased (transient without associated symptoms) in the 100 mg and/or 150 mg groups.

Conclusion: In a population of RA pts with long-standing disease and previous treatment with multiple DMARDs, 12 weeks of treatment with ASP015K was well tolerated and efficacious, with the highest response seen at the 100 and 150 mg doses. These data support further development of ASP015K for the treatment of RA.

Background/Purpose: Little data exist regarding mortality in Ankylosing Spondylitis (AS) patients. We performed a population-based study of diagnoses associated with hospital mortality in AS.

Methods: Data were abstracted from the Healthcare Cost and Utilization Project-National Inpatient Sample (HCUP-NIS) between 2007-2011. We identified hospital discharges with AS using a validated administrative definition. The primary outcome was mortality and we performed a subset analysis on cervical spine fracture (CSFX) associated conditions and fracture level. Chi-square and Wilcoxon rank sum tests were used when appropriate to identify diagnoses associated with mortality. Multivariable logistic regression, including socio-demographic variables, significant covariates and comorbidities, was performed to identify independent factors associated with in-hospital mortality.

Results: There were 12,493 AS admissions, 422 CSFXs and 276 deaths between 2007-2011. The mean age of all hospitalized AS patients was 59.2 ± 16.4 years, 71% were males and 24% were electively admitted. The mean age of those with CSFX was 67.8 ± 15.1 years, 91% were males and 11% were electively admitted. The mean age of those who died was 73.0 ± 12.9 years, 78% were males and 10% were electively admitted. In the multivariable model, bacteremia and CSFX were the diagnoses with the highest odds of death. 7.28 (95% CI: 5.36-9.88) and 5.70 (95% CI: 3.63-8.95), respectively. Of those with CSFX, 66% also had a diagnosis of fall, though there was no interaction between CSFX and falls in predicting mortality. Motor vehicle accidents accounted for another 16% of CSFX cases. The majority of CSFX occurred at the lower cervical spine (75%). Regardless of level of fracture, 11% of patients died with associated CSFX.

Conclusion: The diagnoses most strongly associated with mortality in hospitalized AS patients, were bacteremia and CSFX. CSFX appears to be most commonly associated with falls and the majority of fractures occur in the lower cervical spine. This is the first population-based study describing the significant mortality associated with CSFX in AS patients.

A Physically Demanding Job May Amplify the Effect of Disease Activity on the Development of Syndesmophytes in Patients with Ankylosing Spondylitis. Sofia Ramiro1, A. M. van Tubergen2, Robert Landewe3, Anne-Elies Boonen4, Carmen Stolwijk5, Maxime Douagos6, Filip Van den Bosch7 and Desiree van der Heijde8. 1Amsterdam Rheumatology Center/University of Amsterdam, Amsterdam, Netherlands, 2Maastricht University Medical Center, Maastricht, Netherlands, 3Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, 4Université Paris René Descartes and Hôpital Cochin, Paris, France, 5Ghent University Hospital, Ghent, Belgium, 6Leiden University Medical Center, Leiden, Netherlands.

Background/Purpose: We have recently shown that disease activity is longitudinally associated with radiographic progression in AS. In animal models, it has recently been shown that mice that were tail suspended, in order to prevent mechanical loading on paws, had less new bone formation, thus providing a proof-of-concept that mechanical strain drives new bone formation in spondyloarthritis. Our aim was to investigate the complex relationship between inflammation, mechanical stress and radiographic progression in patients with ankylosing spondylitis (AS), using job type as a proxy for continuous mechanical stress.

Methods: Patients from OASIS were followed-up for 12 years, with 2 yearly assessments. Two readers independently scored the x-rays according to the mSASSS. Disease activity was assessed by the ASDAS-CRP. The relationship between ASDAS and spinal radiographic progression was investigated with longitudinal analysis, with job type at baseline (physically demanding (‘blue collar’) vs sedentary (‘white collar’) labor) as a potential factor influencing this relationship. The effects of smoking status and socio-economic factors were also investigated.

Results: In total, 184 patients were included in the analyses (70% males, 83% HLA-B27 positive, 39% smokers, 48% blue-collar workers (65/136 patients in whom data on job type were available)). The relationship between disease activity and radiographic progression was significantly and independently modified by job type. In ‘blue-collar’ workers vs ‘white collar’ workers every additional unit of ASDAS resulted in an increase of 1.2 vs 0.2 mSASSS-units/2-years (p = 0.014 for the difference between blue collar and white collar workers). In smokers vs non-smokers every additional unit of ASDAS resulted in an increase of 1.9 vs 0.4 mSASSS-units/2-years. Personal income also significantly modified the relationship ASDAS-mSASSS, but smoking status and socio-economic factors were not investigated.

Conclusion: Physically demanding jobs may amplify the driving effects of inflammation on radiographic progression, thus supporting the theory that mechanical stress leads to bone formation in AS. Smoking and personal income are likely classic confounders of this relationship but a separate detrimental effect of smoking on radiographic progression could not be excluded. If confirmed, these findings may have implications for our commonly given advice to patients with SpA to strenuously exercise.

Spondyloarthritis Is Associated with Increased Cardiovascular and Cerebrovascular Mortality. Nigel Haroon1, Nisha Nigil Haroon1, Ping Li1, Michael Paterson1 and Robert D. Inman4. 1Toronto Western Research Institute, Toronto, ON, 2University of Toronto, Toronto, ON, 3Institute of Clinical Evaluative Sciences, Toronto, ON, 4University of Toronto and Toronto Western Hospital, Toronto, ON.

Background/Purpose: OnSpA is a population-based study of spondyloarthritis (SpA) based on a provincial population of over 13 million. Patients with SpA are thought to be at increased risk of cardiovascular disease but it is unknown if they have excess vascular mortality. We explored risk of vascular mortality and the contributing factors in AS.

Methods: We performed a population-based, retrospective cohort study on incident SpA patients, age 15 or above, living in Ontario, Canada between April 1995 and March 2011. There were 21,878 SpA cases and 87,504 controls (matched for age, gender and socioeconomic status). The primary outcome was a composite event of cardiovascular or cerebrovascular death coded as the primary cause on death certificates. Considering the large size of the cohorts, we used standardized differences to compare the baseline characteristics of those with AS and their matched controls. Cox proportional hazards model was used to estimate differences in vascular mortality between cases and controls. Crude and adjusted hazard ratios (HR) were calculated and adjustments were made for coronary and cerebrovascular disease (CAD, CVD), cancer, diabetes, dementia, inflammatory bowel disease, hypertension, chronic kidney disease (CKD) and peripheral vascular disease (PVD). Additionally, we used a separate model in those with AS to identify covariates associated with vascular mortality. Finally, we constructed survival curves using the Kaplan-Meier (KM) method and tested for survival differences among groups using the Log-Rank test.

Results: In the SpA cohort 53% were male, with a mean age of 46 ±16 years, and a follow-up of 169,307 patient-years. Follow-up for controls was 692,499 patient-years. Crude and adjusted HR (95%CI) for vascular deaths were 1.49 (1.26–1.77) and 1.36 (1.14–1.63) respectively, indicating a 36–49% higher risk of vascular mortality in AS. Crude HR (95%CI) in males and females were 1.63 (1.31–2.03) and 1.31 (1.00–1.71) respectively. Cases and controls had similar prevalence of CAD, CVD, PVD, dementia and diabetes, but IBD (6% vs 4%), hypertension (24% vs 18%) and CKD (2% vs 0.8%) were more common in SpA. The predictors of vascular death were age, male sex, low income, CKD and PVD apart from CAD and CVD. The KM curve is shown in Figure 1.

Conclusion: This is the first population-based study to demonstrate SpA is associated with significantly risk of vascular mortality. These new findings should prompt a comprehensive strategy to screen and treat modifiable vascular risk factors in SpA patients.

Follow Up Days

Progression to and Type of Orthopaedic Surgery in Juvenile Vs. Adult-Onset Ankylosing Spondylitis. Deepak R. Jadon1, Gavin Shadick2, Amelia Jobling3, Athinalpaiset V Ramanan4 and Raj Sengupta5. 1Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom, 2University of Bath, Bath, United Kingdom, 3University of Bristol Hospital Trust, Bristol, United Kingdom.

Background/Purpose: Juvenile-onset ankylosing spondylitis (JoaS) and adult-onset ankylosing spondylitis (AoS) are subtypes of ankylosing spondylitis (AS) that may have different clinical outcomes. We compared cohorts of JoaS and AoS in terms of: (1) clinical characteristics; (2) clinical outcomes; (3) proceeding to and types of AS-related orthopaedic surgery.

Methods: A cohort study was conducted of all patients attending a dedicated AS clinic in a teaching hospital. Patients aged <16 years at symptom onset were categorised as JoaS, and ≥17 years as AoS. Demographics, clinical parameters, composite indices ≤6 months of census, biological use, and history of AS-related orthopaedic surgery to the spine, root or peripheral joints were recorded. Univariate, multivariate logistic regression, and survival analyses were performed.

Results: 533 AS cases were studied: 162 JoaS; 391 AoS. On univariate analyses (Table 1), no statistically significant differences were found between JoaS and AoS in terms of HLA-B27 positivity, smoking, occurrence at any time of inflammatory bowel disease, psoriasis, enthesitis, or uveitis. JoaS cases had higher scores for two Bath AS Functional Index (BAFI) domains: bending forward from the waist (p=0.03); doing physically demanding activities (p=0.04). On multivariate analyses adjusted for significant covariates (Table 2), compared to JoaS cases the AoS cases were less likely to have: proceeded to surgery (odds ratio, OR 0.31; p<0.001); had a hip procedure (resurfacing or arthroplasty; OR 0.374; adjusted p=0.001); had an arthroplasty (OR 0.43; adjusted p=0.012). JoaS and AoS were equally likely to have had hip resurfacing, bilateral hip arthroplasty, hip arthroplasty revision, hip arthroplasty re-revision, spinal orthopaedic surgery, and several (≥3) procedures.

Kaplan-Meier survival curves (log-rank test p=0.001) and Cox regression also demonstrated a significant difference in not having surgery between JoaS and AoS (p=0.002) (Figure 1). A history of smoking was not associated with surgery. AS cases with older age at symptom onset were far less likely to have surgery than those with younger onset, in a non-linear manner.

Conclusion: JoaS are more likely than AoS cases to proceed to AS-related orthopaedic surgery, especially hip resurfacing and arthroplasty.

**Background/Purpose:** Previous studies have shown that the risk of vertebral fractures is increased in patients with ankylosing spondylitis (AS). Prospective longitudinal data about radiographic vertebral fractures are scarce and little is known about the effect of tumor necrosis factor-alpha (TNF-α) blocking therapy on the development of vertebral fractures in AS.

**Objectives:** Our objective was to determine the prevalence of radiographic vertebral fractures in patients with AS before start of TNF-α blocking therapy and to investigate the incidence of vertebral fractures after 4 years of follow-up.

**Methods:** Consecutive AS patients from the Groningen Leeuwarden AS (GLAS) cohort with available thoracic and lumbar radiographs at baseline and after 4 years of TNF-α blocking therapy were included. Patients fulfilled the modified New York criteria for AS and the ASAS criteria to start with TNF-α blocking therapy. Vertebral fractures were assessed by two independent readers using the Genant method and were defined as moderate vertebral fractures at baseline were significantly associated with the development of new fractures. Lumbar spine and hip BMD showed significantly less improvement in lumbar spine BMD than patients without new fractures (median change in Z-score 0.4 vs. 0.8).

**Conclusion:** The prevalence of radiographic vertebral fractures was 26% in AS patients with active disease before start of TNF-α blocking therapy. Although a significant increase in BMD was found, 20% of patients developed new vertebral fractures during 4 years of TNF-α blocking therapy.

SM 101, a Novel Recombinant, Soluble, Human FcγRIIB Receptor, in the Treatment of Systemic Lupus Erythematosus: Results of a Double-Blind, Placebo-Controlled Multicenter Study. Sascha Tillmanns1, Claudia Kolli- ligs1, David P. D'Cruz2, Andrea Doria3, Eric Hachulla4, Reinhard E. Voll5, L. E. Kristensen5, AbbVie, 8, UCB, 8; Disclosure: E. Liebisch1, 2, L. T. Jacobsson1, Klaus Schollmeier1. 1SuppreMol GmbH, Martinsried, Germany, 2Louise Coote Lupus Unit, Guy’s and St Thomas’ Hospital, London, United Kingdom, 3University of Padova, Padova, Italy, 4Lille University, Lille, France, 5University Hospital Freiburg, Freiburg, Germany.

Background/Purpose: SM 101, which represents the human soluble non-glycosylated version of the Fcγ receptor IIB, binds to the Fc part of autoimmune complexes and inhibits the binding of immune complexes to cell-binding Fcg receptors. It has undergone preclinical and clinical safety and efficacy investigation, with evidence of efficacy in primary immune thrombocytopenia. The mode of action could make SM 101 a safe and effective treatment for systemic lupus erythematosus (SLE).

Methods: The objectives of this phase IIa randomised, double-blind, placebo-controlled parallel-group study were to evaluate the safety, tolerability and efficacy of placebo and 2 doses of SM 101 (6mg/kg and 12mg/kg), randomised 1:2:2, in patients with SLE. The main inclusion criteria were a diagnosis of SLE, evidence of serological activity (high anti-dsDNA activity or low C3), and a SELENA-SLEDAI score ≥ 6 points, with stratification to include patients with lupus nephritis (LN). Concomitant immunosuppressive therapy with corticosteroids, mycophenolate mofetil (MMF) or azathioprine and adjuvant SLE medication were allowed at constant doses during the study. Eligible patients received an infusion of study drug once a week for the first 4 weeks; study duration was 24 weeks. Data were reviewed regularly by an independent safety monitoring board. Response was measured at 24 weeks according to the SLE Responder Index (combination of SELENA-SLEDAI score ≥ 4 points, no BILAG A or 2 × B flares and no PGA score worsening).

Results: Fifty one eligible patients, 14 with LN, from 8 European countries and Australia, were randomized and received at least one dose of active investigational drug or placebo. Concomitant medications were corticosteroids (96% of patients), MMF (45%), azathioprine (20%) or combinations thereof. Patient numbers per group and response rates are shown in Table 1. The SLE Responder Index response rate was twice as high in the SM 101-treated patients compared to placebo, and response in patients with LN was proportionately greater. The response rate on SM 101 remains the same after exclusion of 15 patients who received rescue medication. The main clinical drivers for response were improvement in arthritis and in skin eruption (present in 75% and 50% patients respectively) according to the BILAG scale. Both worsened or remained unchanged in placebo patients; in SM 101-treated patients improvement or resolution occurred in 57% with arthritis and 45% with skin eruption. No safety signals which could be attributed specifically to SM 101 were reported, and no serious adverse events were probably or possibly related to the drug. No anti-drug antibodies were detected.

Conclusion: The encouraging results of this early phase study indicate that the novel biological SM 101 warrants further investigation as a treatment for patients with SLE, including patients with LN.

*A last-observation-carried-forward procedure was used to impute missing values if a pt had data for <3 post-baseline evaluation. Of 21 randomized pts, 20 were included in the efficacy analyses.

Meaningful reduction in proteinuria was defined as P/C (protein/creatinine) ratio < 0.5 for non-nephrotic pts; and >50% reduction in P/C ratio and P/C ratio < 3.0 for nephrotic pts.

**Background/ Purpose:** To conduct secondary endpoint analyses of the effects of subcutaneously-administered blisibimod (A-623, AMG 623), an inhibitor of B-cell activating factor (BAFF), on patient-reported outcomes and indices of disease activity in patients with systemic lupus erythematosus (SLE) during the phase 2b clinical trial PEARL-SCL (NCT01162681).

**Methods:** 547 SLE patients who met the ACR classification criteria, and had >40% anti-double-stranded DNA or anti-nuclear antibodies, and SLENA-SLEDAI score ≥6 at baseline, were enrolled into the PEARL-SCL study, and randomized 1:1 to receive placebo or blisibimod administered at 1 of 3 dose levels, 100 mg weekly (QW), 200 mg QW, or 400 mg every 4 weeks for up to 52 weeks (with a median of 37 weeks) or until the last subject completed 6 months of study drug therapy. Patient self-reported outcomes were evaluated using the Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue scale, and disease activity evaluated within SLENA-SLEDAI organ domains.

**Results:** Significant improvements in measures of disease activity, including the SLE responder Index-8 (SRI-8) in subjects with severe baseline disease (defined at SLENA-SLEDAI score=10 and receiving steroids), especially at the highest blisibimod dose of 200mg QW were reported previously (Furie et al. 2014). A proximately 76% of subjects had SLENA-SLEDAI musculoskeletal organ involvement at enrollment, and 89% of subjects had mucocutaneous organ involvement. At Week 24, approximately 12% and 39% of subjects randomized to the 200mg QW blisibimod arm had musculoskeletal or mucocutaneous organ involvement, compared with approximately 15% and 42% respectively in the placebo arm (p<0.2 to p<0.05 across manifestations evaluated over Weeks 12 through 24). A concomitant tendency toward improved self-reported fatigue was observed amongst subjects randomized to blisibimod based on the FACIT-Fatigue scale, especially in the 200mg QW group (N=80) where a mean 6.9-point improvement in baseline from week 24 (p=0.065) compared with 4.4 with placebo (N=229). Based on exploratory statistical analyses, the
Effects of blisibimod on FACIT-fatigue were significantly better than placebo \((p=0.05)\) as early as Week 8.

Blisibimod was safe and well-tolerated at all dose levels with no meaningful imbalances in serious adverse events or infections between blisibimod and placebo. Amongst the commonly-reported AEs, imbalance was observed only with injection site reactions \((200\, \text{mg} \times \text{QW blisibimod}=15\%, \text{matched placebo}=7\%)\, but these were not severe or serious.

**Conclusion:** Fatigue remains a debilitating manifestation of lupus. In this trial, blisibimod showed a tendency toward improved mucocutaneous and musculoskeletal disease activity as well as patient self-reported fatigue. These data support further evaluation of blisibimod in patients with SLE.

**Results:** In the first treated patient, disease activity rapidly decreased already after one treatment cycle, while in the second patient a reduction in disease activity was observed two weeks later. During the following treatment cycles disease activity further decreased or remained low due to disappearance of clinical manifestations such as arthritis, myositis and skin rash.

Addition and unexpectedly levels of anti-dsDNA-antibodies considerably decreased in both patients. The clinical response was associated with cyclic and treatment-related increases of the CD25hiFoxp3+CD127lo Treg population in the peripheral blood. The therapy was very well tolerated and adverse events were generally mild and transient.

**Conclusion:** These data provide the first evidence for the clinical efficacy of low-dose IL-2-therapy in conjunction with the boosting of Treg activity in SLE and strongly support the rationales of this selective biological treatment strategy.

**Exploratory Analysis of Pharmacokinetic Effects of Atacicept in Patients with Moderate to Severe Systemic Lupus Erythematosus.**

David Wofsy, Caroline Gordon, Yong Li, Stephen D. Wax and David Isenberg.

**Background/Purpose:** Atacicept is a fusion protein that inhibits B-cell stimulating factors BLYS and APRIL. We previously reported the clinical effects of atacicept in lupus patients with active disease (the APRIL-SLE study). Here we report the exploratory analysis between mean drug concentration and clinical outcome in those subjects.

**Methods:** Patients with active SLE \((\geq 1 \text{ BILAG A and/or B})\) were treated with corticosteroid taper for 12 weeks. Subjects reaching BILAG C or D at weeks 10 and 12 were randomized 1:1:1 to receive placebo (PLC), atacicept 75 mg \((A75)\) or 150 mg \((A150)\) twice weekly for 4 weeks then weekly for 48 weeks. All patients received standard of care. As previously reported, A150 reduced the frequency of BILAG A and B flares but was discontinued prematurely due to two infection-related deaths. This post-hoc analysis was performed among subjects in all groups randomized at least 52 weeks prior to discontinuation of A150 and who had an opportunity to complete the protocol \((n=81, 84, and 81 for \text{PLC, A75, and A150, respectively})\). For this analysis subjects in the two treatment arms were divided into four quartiles based on mean atacicept concentration, the 1st being the group with the lowest concentration.

**Results:** Subjects with the highest atacicept concentrations \((3rd and 4th quartiles)\) experienced fewer flares during treatment compared to subjects with lower concentrations \((1st and 2nd quartiles)\) and subjects in the PLC group \((60, 63, 61, 49, and 29\% for PLC, A75, and A150, respectively). For this analysis subjects in the two treatment arms were divided into four quartiles based on mean atacicept concentration, the 1st being the group with the lowest concentration.

**Conclusion:** These data provide the first evidence for the clinical efficacy of low-dose IL-2-therapy in conjunction with the boosting of Treg activity in SLE and strongly support the rationales of this selective biological treatment strategy.

**Disclosure:** J. Y. Humrich, None; C. von Spee-Mayer, None; E. Siegert, None; A. Rose, None; T. Alexander, None; F. Hiepe, None; A. Radbruch, None; G. Burmester, None; G. Riemekasten, None.
Results: A recently developed imaging tool (Science Translational Medicine 2014, 6:230) was used to quantify the frequency of CD20+ B and CD4+ T cells expressing the anti-apoptotic molecules BCL-2, MCL-1, and the pro-apoptotic molecule BIM. In primary follicles of normal tonsils, both B and T cells frequently expressed BCL-2. However, upon entry into germinal centers (GC), BCL-2 was down-regulated and MCL-1 was induced. In marked contrast, in LuN and MRTI biopsies, the frequency of BCL-2+ cells was increased in B and T cells while MCL-1+ cells were rare. Observed differences between tonsil GC lymphocytes versus TII in LuN and MRTI for both BCL-2 and MCL-1 were highly significant (p<0.001). These expression differences were confirmed by laser capture microscopy coupled to qPCR. In contrast, the frequency of BIM+ cells did not significantly vary among tissues. Consistent with these findings, BCL-2, but not MCL-1 expressing cells were detected in the infiltrated kidney in IFN-α-induced NZB/W F1 lupus mice. Furthermore, administration of ABT-199, a BCL-2 selective inhibitor, prevented the development of lupus nephritides by depleting intra-renal B and T cells in these animals.

Conclusion: Frequent BCL-2, but not MCL-1, expressing cells were present in LuN, MR TII tissues and IFN-α-induced NZB/W F1 lupus mice. Treatment of these mice with the BCL-2 selective inhibitor ABT-199 resulted in the loss of renal B and T cells and the preservation of renal function. These data indicate that BCL-2, which is dysregulated in TII, is an attractive therapeutic target in cases of lupus nephritis manifesting tubulointerstitial inflammation.

Targeting the RhoA-Rock Pathway to Reverse T Cell Dysfunction in SLE.

Cristina T. Rozo, Laura Leuenberger, Kyriakos A. Kirou, Margaret R. Robotham, Sanjay Gupta, Reena Khiayan, Alessandra B. Pernis and Jane E. Salmon.

Hospital for Special Surgery, New York, NY.  

Background/Purpose: Aberrant expansion of Th17 cells and deregulated production of IL-17 and IL-21 are involved in the pathogenesis of SLE. Production of IL-17 and IL-21 is critically dependent on the transcription factor, IRF4 (Interferon Regulatory Factor 4). Rho-associated protein kinases (ROCKs) can phosphorylate IRF4 and regulate its activity. The finding that ROCK activity is elevated in SLE patients and is associated with human Th17 differentiation, coupled with the ability of ROCK inhibitors to ameliorate autoimmunity in murine models of lupus suggest that targeting the ROCK pathway might be a novel therapeutic strategy for the treatment of SLE. ROCK activation can be inhibited by Y27632 (a nonselective ROCK inhibitor) and Y27632 can reverse SLE in a mouse model of lupus via ROCK1 and ROCK2) or by ROCKs (which inhibit ROCKs by interfering with their major upstream activator, RhoA). Here, we examined the ability of Y27632 and simvastatin to inhibit the production of IL-17 and IL-21 by human T cells.

Methods: We assessed the capacity of Y27632 (60μM-90μM) and simvastatin (0.2μM) to decrease ROCK activation and IL-17 and IL-21 production by cord blood CD4+ T cells cultured under Th17-skewing conditions (5nM IL-6, 10ng/mL TGFβ, 20ng/mL IL-1β, 50ng/mL IL-23, 5ug/mL anti-IL-4 and 10ug/mL anti-IFN-g). We also assessed the ability of Y27632 and simvastatin to diminish IL-17 and IL-21 production by stimulated SLE CD4+ T cells. ROCK activation was determined by an ELISA-based ROCK activity assay. Plasma levels of IL-17, IL-21, and CCL20 were measured by ELISA. qPCR was used to determine gene expression of IRF4. All patients (N=24) met ACR criteria for SLE. Demographics and clinical features were as follows: mean age 37 ± 11 years, 96% female, 8% Asian, 21% African American, 21% Caucasian, 50% Hispanic, SLEDAI score 6 ± 4, and 42% with nephritis.

Results: Compared to Th0 cells, cord blood CD4+ T cells cultured under Th17-skewing conditions exhibited elevated ROCK activity that was inhibited by both Y27632 and simvastatin. IL-17 production was decreased by 60% in cord blood Th17 cells treated with either inhibitor. IL-21 production was decreased by 83% (90μM Y27632) and 65% (0.2μM simvastatin) in cord blood Th17 cells. Neither Y27632 nor simvastatin decreased IRF4 gene expression suggesting that their effects on IL-17 and IL-21 were not secondary to effects on cell viability. Both Y27632 and simvastatin decreased IL-17 and IL-21 cytokine production by purified SLE CD4+ T cells but neither treatment altered IFN-γ protein production. We also confirmed our
previous findings that in a subset of SLE patients PBMCs showed elevated ROCK activity compared to PBMCs from healthy controls. In this new cohort, the majority (79%) of the SLE patients had ROCK values that were at least 2SD above the mean ROCK value for the healthy controls.

**Conclusion:** These data indicate that the production of IL-17 and IL-21 by SLE T cells can be selectively inhibited by targeting the RhoA-ROCK pathway providing a rationale to inhibit the ROCKs as a means to reverse T cell dysfunction in SLE.

**2841** Identifying Novel Lupus Severity Risk Variants through Identification of Alleles with High Ethnic Variability Worldwide.

**Background/Purpose:** Substantial epidemiologic evidence demonstrates that SLE disproportionately affects minority patients in terms of incidence, prevalence, and disease severity. European ancestry has been associated with a lower risk of developing renal disease in SLE. We developed an approach to identify novel SLE risk variants that may influence disease severity by searching for single nucleotide polymorphisms (SNPs) with high ethnic variability worldwide and testing them in our multiethnic SLE cohort.

**Methods:** The Human Genome Diversity Project (HGDP) characterized the allele frequency of 650,000 SNPs in 938 people from 53 populations worldwide. Our multiethnic cohort of SLE patients was genotyped on the Illumina Immunochip (I-chip), covering over 160,000 SNPs across 185 autoimmune genes plus select non-autoimmune genes and ancestry informative markers. There were 32,907 SNPs common to the HGDP and I-chip. We selected the top 2% of those SNPs that met both an absolute mean frequency difference and a t-test criteria between Europeans and Non-Europeans. We tested these SNPs in our multiethnic cohort of 1427 SLE patients for severe disease outcomes (renal disease by ACR renal criterion, severe renal disease on biopsy or end-stage renal disease, and production of dsDNA antibodies) stratified by ethnicity: Caucasian, African American, Hispanic, and Asian. Logistic regression was performed, adjusting for disease duration and gender. Ethnic strata were refined via STRUCTURE analysis of 878 I-chip SNPs, stratified by ethnicity: Caucasian, African American, Hispanic, and Asian. Linkage disequilibrium (LD) (r2 0.8), p<0.001. Most significantly 4.5e-05).

**Results:** This approach identified 13 SNPs with ethnicity-disease outcome associations (unadjusted p value < 0.001). Two SNPs, rs2099365 and rs2163882, which are in high linkage disequilibrium (LD) (r2 = 0.98) in Hispanics, also had significant false discovery rate p values (0.014) for association of renal disease in Hispanics (odds ratio 2.9). Both SNPs are 20kb from the 3’ end of the endomucin (EMCN) gene, a glycoprotein involved in cell adhesion. These SNPs are predicted to disrupt 3-4 regulatory motifs. The EMCN gene is a non-autoimmune gene on the I-chip, not previously associated with SLE, but recently reported to be associated with susceptibility to RA. The association of the 2 SNPs with renal disease in Hispanics is consistent with an estimated 5.7 odds of renal disease per 100% Amerindian ancestry (p = 3.5e-06) compared to 0.17). In addition, Cpg-induced IFN production from PBMCs was inhibited by 65% (p = 0.0001) compared to isotype control but was not inhibited by pretreatment with Fab’ (122.3 ± 27.7%, p = 0.78). The IFN gene score was elevated in SLE (3.1 ± 0.46) compared to healthy (1.49 ± 1.1, p = 0.07) donors. Cpg-induced upregulation of the IFN gene score (3.9 ± 0.9) was reduced by pretreatment of PBMCs with Cpg at 0.9 ± 1.9, p = 0.12).

**Conclusion:** A mAb targeting CD123 (CSL362) depletes pDCs and decreases Cpg-induced IFNα production and IFNα-inducible gene expression from SLE and healthy donor PBMCs. These effects were not seen with IL3 blockade alone or isotype control mAb. Cytoreductive therapy with CSL362 may therefore represent a novel treatment strategy in SLE.

**Disclosure:** S. Oon, CSL Limited, 2; N. Wilson, CSL Limited, 3; I. Wicks, CSL Limited, 2.

**2842** An Anti CD123 Monoclonal Antibody (CSL362) Depletes Plasmacytoid Dendritic Cells and Inhibits CpG Upregulated IFNα Production and IFNα-Inducible Gene Expression in Peripheral Blood Mononuclear Cells from Patients with Systemic Lupus Erythematosus. Shereen Oon, N. Wilson,1 J. Molineros,1 and Ian Wicks,2 1The University of Melbourne, Melbourne, Australia; 2The Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia.

**Background/Purpose:** Plasmacytoid dendritic cells (pDCs) contribute to systemic lupus erythematosus (SLE) pathogenesis by producing Type 1 interferon (IFN), most likely induced by endosomal Toll like receptor (TLR) activation by immune complexes. In healthy donors, pDCs are known to express high levels of CD123, the IL3 receptor alpha chain. CSL362 is a novel monoclonal antibody (mAb) that binds to CD123, neutralizing IL3 signaling and causing antibody dependent cell mediated cytotoxicity (ADCC) of CD123 bearing cells. This study of SLE and healthy donors evaluates 1) CD123 expression on pDCs and other cell types, 2) CSL362 mediated depletion of pDCs, and 3) the effect of CSL362 on IFNα production and IFNα-inducible gene expression from peripheral blood mononuclear cells (PBMCs) in vitro.

**Methods:** Quantitative flow cytometry with Quantibrite PE beads and an anti-CD123-PE antibody was used to assess CD123 expression on cell types from peripheral blood of SLE and healthy donors (n=15). PBMCs from SLE (n=13) and healthy (n=10) donors were isolated by Ficoll gradient centrifugation and incubated for 24 hours in vitro with CSL362, the Fab portion of CSL362 (Fab,), which neutralizes IL3 signaling, but does not effect ADCC, or an isotype control mAb. The percentage of viable pDCs was enumerated by flow cytometry. PBMCs from SLE (n=7) and healthy (n=6) donors were pretreated with CSL362, Fab’ or isotype control mAb for 24 hours, then stimulated with CpG, a TLR9 agonist, for 18 hours. IFNα production from culture supernatant was assessed by ELISA. A novel ‘IFN gene score’, based on 11 IFNα-inducible genes, was incorporated into a customized gene array, to serve as a “gene signature” to stratify patients and assess drug efficacy. This score was evaluated by performing quantitative PCR on RNA extracted from SLE (n=17) and healthy (n=9) donor whole blood. The average of the log2 fold change for the 11 genes in the SLE patients was compared to healthy donors. This score was also evaluated in PBMCs (n=2), n=2 healthy) after CSL362 pretreatment followed by CpG stimulation. The average of the log2 fold change for the 11 genes of the treated samples was compared to the untreated samples.

**Results:** CD123 expression levels were highest on pDCs compared to other cell types. pDCs were depleted after in vitro culture with CSL362 (8.3±2.4% [mean±SEM], p<0.0001) compared to isotype control but were not depleted by Fab’ (96.8±5.5%, p=0.17). In addition, Cpg-induced IFN production from PBMC was inhibited by CSL362 pretreatment (11±8%, p<0.0001) compared to isotype control, but was not inhibited by pretreatment with Fab’ (122.3±27.7%, p=0.78). The IFN gene score was elevated in SLE (3.3±0.46) compared to healthy (1.49±1.1, p=0.07) donors. Cpg-induced upregulation of the IFN gene score (3.9±0.9) was reduced by pretreatment of PBMC with CSL362 (1.9±1.9, p=0.12).

**Conclusion:** A mAb targeting CD123 (CSL362) depletes pDCs and decreases Cpg-induced IFNα production and IFNα-inducible gene expression from SLE and healthy donor PBMCs. These effects were not seen with IL3 blockade alone or isotype control mAb. Cytoreductive therapy with CSL362 may therefore represent a novel treatment strategy in SLE.

**Disclosure:** S. Oon, CSL Limited, 2; N. Wilson, CSL Limited, 3; I. Wicks, CSL Limited, 2.

**2843** SLE Patients Carrying a Disease-Associated PTPN22 R620W Variant Show Reduced Interferon-Inducing Capacity.

Yaya Wang, David Ewart, Ami Y amamoto, Emily C. Baechler, Parastoo Fazeli and Erik J. Peterson. University of Minnesota, Minneapolis, MN.

**Background/ Purpose:** Type 1 interferons (IFN) are implicated in the pathogenesis of systemic lupus erythematosus (SLE). Increased expression of IFN-regulated genes, termed the IFN-signal, correlates with autoantibodies and disease activity in SLE. Likely sources of type 1 IFN in SLE include plasmacytoid dendritic cells (pDC), which produce IFNα following Toll-like receptor 7 (TLR7) activation. A coding variant in the protein tyrosine phosphatase nonreceptor type 22 (PTPN22) gene is associated with SLE. PTPN22 encodes lymphoid tyrosine phosphatase (Lyp). We showed previ-
ously that Lyp is required for TLR-driven type 1 IFN production in myeloid cells. Variant PTPN22 encodes an R620W bearing protein ("LypW"). We recently established that LypW is associated with impaired TLR-driven type 1 IFN production and type 1 IFN-dependent immunity. However, the functional consequences of LypW carriage in human SLE patients remain unclear. The current study was designed to address the effect of LypW carriage on interferonogenic TLR signaling in SLE patients.

**Methods**: Caucasian SLE patients satisfying 1987 ARA diagnostic criteria were genotyped for PTPN22 LypW variant carriage. Plasma IFNα concentrations in 15 LypW carriers and 21 non-carriers were determined by ELISA. IFNα gene signature in whole blood was also determined by quantitative PCR (qPCR). PBMC were stimulated with R848, a TLR7/8 agonist, and IFNα2 and TNFα expression in pDC (Lin−HLA-DR−CD123+) were detected by FACS. We measured IFNα protein levels in the supernatant from R848-stimulated SLE PBMC by ELISA. We compared STAT1 activation in SLE PBMC from carriers and non-carriers by phospo-flow.

**Results**: In both LypW carrier and non-carrier SLE patients, we observed comparable IFNα protein in plasma and type 1 IFN "signatures" in whole blood. We found that the percentage of pDC that produce IFNα2 after R848 stimulation was significantly reduced in LypW carrier SLE patients, while the percentage of pDC producing TNFα was comparable to that observed in non-carrier patients. Further, we observed that IFNα2 expression in pDC was decreased in LypW carriers. Supematant IFNα protein levels from R848-stimulated PBMC were significantly reduced in LypW carriers. Moreover, activation of type 1 IFN-driven STAT1 was impaired in LypW carrier PBMC after R848 stimulation.

**Conclusion**: LypW carrier SLE patients have reduced capacity for TLR-induced type 1 IFN production, even as they exhibit elevated whole blood IFNα2 protein similar to those observed in non-carrier patients. The findings suggest that LypW carriage may identify a subset of SLE patients who harbor defects in type 1 IFN-dependent host defense or anti-inflammatory functions.

**Intracellular Complement C3 Is Exposed on the Cell Surface upon Apoptosis Induction and Participates in the Clearance of Apoptotic Cells By Phagocytes.**

Lucrezia Colonna1, Christian Lod2, Yu-Feng Peng2, Xi-zhang Sun1, Lena Tanaka3, Sandip Panicker2 and Keith E. Elkon1.1 University of Washington, Seattle, WA, 2True North Therapeutics, South San Francisco, CA.

**Background/Purpose**: The complement system has been viewed as a predominantly serum-derived host defense mechanism with multiple functions, including clearance of apoptotic cells. Defective function of the complement pathways have been implicated in the pathogenesis of systemic lupus erythematosus (SLE). Recently, intracellular complement C3 storage was demonstrated in many different cell types, and C3 activation products were shown to participate in the survival and effector cell differentiation of murine and human lymphoid cells. Despite the known role of serum-derived C3 activation products in the removal and immunosuppressive properties of dying cells, the role of intracellular C3 in clearance of apoptotic cells has never been explored. Thus, we asked whether human cells expose C3 and/or C3 activation products on their surface upon cell death induction, and whether such exposure functionally participates in their phagocytic clearance, independently of serum complement factors.

**Methods**: Apoptosis and secondary necrosis of human lymphoid cells was induced by both UV irradiation and serum starvation. C3/C3b/C3bi surface and intracellular expression on live and apoptotic human T and B primary cells as well as cell lines was monitored by flow cytometry (FACS), western blot and confocal microscopy. Macrophages were derived from circulating CD14+ monocytes by culture with M-CSF. Phagocytosis of apoptotic cells in presence or absence of serum was quantified by microscopy (phagocytic index) and by FACS with the aid of fluorescently labeled apoptotic cells.

**Results**: We observed that live human primary T and B cells, and human T and B cell lines expressed intracellular but not cell surface C3/C3b. However, upon apoptosis induction, C3 activation products were exposed on the surface of dying cells in a time dependent manner. Detection of C3/C3b correlated with later stages of apoptosis characterized by cell shrinkage and loss of membrane integrity (Annexin V+ PI+ cells). Confocal microscopy of unfixed cells revealed detection of C3/C3b in a granular distribution, possibly in blebs and/or other endosomal compartments. To determine whether surface-exposed C3/C3b had functional relevance, we blocked the macrophage C3bi receptors CR3 and CR4 with antibodies, and compared phagocytosis of apoptotic cells in the absence of serum. Strikingly, functional blockade of CR3 and CR4 on human macrophages in the absence of serum specifically reduced the uptake of C3bi+ late apoptotic cells, and not that of latex beads (with an inhibition of 19.3% for CR3, 21.4% for CR4, and 48% for CR3+CR4 blockade; p = 0.182, 0.066 and 0.043, respectively).

**Conclusion**: Our results suggest that we have uncovered a novel function of intracellular complement C3 activation products in the removal of dying cells. C3 is a very large protein of 185,000 molecular mass and penetration into tissues is likely to be limited. Cell intrinsic, serum-independent, C3-mediated clearance of apoptotic cells may therefore be of particular relevance in tissues where there is accumulation of dead cells as observed in patients with SLE, as well as under other conditions such as hypoxia reperfusion injury and stroke.

CaMK4 Inhibition Ameliorates the Development of Th17 Driven Inflammatory Disease through an IL-17-dependent mechanism.

Background/Purpose: IL-17 producing T helper (Th17) cells have been closely associated with the development of organ damage in inflammatory and autoimmune diseases. We have previously shown that Calcium/calmodulin-dependent protein kinase IV (CaMK4) plays a crucial role in Th17 cell differentiation in vitro and in vivo and suggested that CaMK4 inhibition ameliorates clinical and pathological findings in experimental autoimmune encephalomyelitis (EAE) and MRL/lpr mice (1). We have also shown that iNOS-1 is important in the expression of anti-glomerular basement membrane Ab-induced glomerulonephritis (AIGN) (2). However, the effect of CaMK4 on recruitment of pathogenic T cells to target tissues in inflammatory settings has not been studied.

Methods: To determine the role of CaMK4 in the infiltration of inflammatory cells to target tissues, we induced experimental AIGN in CaMK4 sufficient or deficient mice and compared the kidney injury including the number of IL-17 producing cells in both groups. We also evaluated the effect of KN-93, a compound of CaMK4 antagonist in this AIGN model.

Results: CaMK4 deficient mice displayed less glomerular injury and less protoporphyrin IX (PPIX) at day 34 and at day 21 after induction of AIGN. Kidney infiltration by Th17 producing CD4 T cells was decreased significantly in CaMK4 deficient mice, suggesting that CaMK4 facilitated AIGN damage by promoting local inflammatory cells accumulation. In line with these observations, KN-93 treatment improved clinical and pathological findings in mice induced AIGN at dose dependent manner.

Conclusion: Collectively, our results indicate that CaMK4 inhibition might be a novel therapeutic strategy of Th17 cells-mediated inflammatory diseases.

Survivin Co-Ordinates Formation of Follicular T-Cells in Rheumatoid Arthritis.

Survivin is a proto-oncogene that regulates cell division and apoptosis. Recently, survivin has emerged as a biomarker of persistently active and joint destructive rheumatoid arthritis (RA). High serum levels of survivin are frequently associated with antibodies against cyclic citrullinated epitopes (ACPA). Here we study the role of survivin in the formation of follicular T-cells and in the antibody production in RA.

Methods: The intracellular expression of survivin and Bcl-6 was studied in RA patients (age 21-71 years, disease duration 1-49 years) by flow cytometry and qPCR. DNA binding of survivin and Bcl-6 was studied in in RA patients (age 21–71 years, disease duration 1–49 years) by flow cytometry and qPCR. DNA binding of survivin and Bcl-6 was studied in the antibody production in RA.

Results: The sSurv-RA group (n=76) was characterized by higher frequency of RF+ and ACPA+ patients, as well as by higher levels of ACPA compared to sSurv-RA (n=68). Intracellular survivin was present in the effectors (CD45RA+CD27+) CD4+ T cells. Survivin co-expressed with Bcl-6 on lymphocytes of arthritic mice and in RA patients. Bcl-6+ subset comprised 7-38% of surv-CD4+ T-cells and was also CXCR5+. Bcl6+ Surv+ subset of CD4 T cells and mRNA levels of Bcl-6 were lower in blood of sSurv+ patients.

Conclusion: Follicular (CXCR5+PD-1+) CD4 population in spleen and lymph nodes of arthritic DBA1 mice were mostly surv-Bcl6+. Mice treated with survivin-derived peptides developed the phenotype similar to sSurv+ RA patients and had high serum levels of survivin and higher levels of aCII and RF antibodies. Surv- vaccinated mice had significantly increased survivin expression and the subset of surv-Bcl6+ within CXCR5+CD4+ cells in LN. shSurv-treated mice had reduced CD4+surv+ and CD19+surv+ populations in spleens, and smaller CXCR5+CD4+ and CXCR5+B220+ populations. While Bcl-6 gene transcription was increased, inhibiting survivin led to reduced levels of anti-CII antibodies and lower RF, suggesting insufficient Bcl-6 and poor Th17 development. Chromatin immunoprecipitation showed that survivin binds within Bcl-6 responsive element of Blimp-1 promoter potentially controlling transcriptional activity of Bcl-6.

T-Cell Signaling Defects Can Be Corrected By Manipulating ‘TCR Signal Fine Tuning’ Molecules That Are Altered Due to Increased Ubiquitination in Systemic Autoimmune Disease.

Background/Purpose: T-cell selection in the thymus is primarily determined by the avidity of T cell receptor (TCR) for self-ligand-MHC. Since this process is dependent on the somatically generated receptors against the internal antigenic environment, all T cells are inherently self-reactive to some degree. Hence, a signaling threshold must be established whereby overtly high self-avidity, potentially pathogenic, T cells are removed, while allowing other lower self-avidity T-cells to survive. Using a avidity-based TCR transgenic model system, we found that besides the TCR, there are other signal regulating molecules that play a role in establishing signal threshold during thymic selection known as TCR tuning, which controls the intensity of TCR signaling (Pinkhasov et al, manuscript in preparation). Here, we determined the expression of potential TCR signal fine-tuning (TFT) molecules in a model of multi-system autoimmune disease, and investigated their role in T-cell signaling defects and mechanisms of their alteration.

Methods: The availability of murine strains that develop autoimmune disease resembling human SLE enables one to study the preclinical events in the pathogenesis. Here, we used MRL/MpJ-Fas-/- (MRL/+/-) mice that develop SLE at 8–10-months of age, congenic MRL/MpJ-Fasgrgpr (MRL/ppr) mice that develop accelerated SLE due to a mutation of the fas gene, and MHC-matched C3H control mice. To analyze TFTs in antigen-specific T cells, studies were repeated in MRL/ppr, MRL/+/- and healthy B10.BR mice carrying the AND TCR transgene.

Results: We found the altered expression patterns of a battery of TFTs on thymocytes from MRL/ppr and MRL/+/- mice compared to C3H controls; specifically, negative regulator TFTs were reduced, while positive regulator was increased. Thymocytes from young MRL/+/- and MRL/ppr mice showed increased activation and phosphokinase signal upon ex vivo stimulation, which were restored to near normal levels in the presence of a CDS agonistic antibody. Unexpectedly, we observed a drastic reduction of TFTs in activated peripheral T-cells after disease onset. The reduced levels of negative TFTs correlated with increased responsiveness to TCR stimulation and to weak antigenic ligands. The reduced expression of TFTs in periphery was not due to their decreased transcripts, but rather, to activation-induced post-translational modification due to increased ubiquitination leading to targeted protein degradation. This was associated with an altered expression of E3 ubiquitin ligases CIITA, Tra1-81, and Hc1 in MRL mice.

Conclusion: These results suggest that T-cells are able to tune the expression levels of TFTs post-development, likely by targeted protein degradation using the ubiquitin cycling pathway. We propose that the ability of T-cells to alter their internal signal threshold by altering TFP expression is a novel mechanism for
T-cells to escape peripheral tolerance and perpetuate autoimmune disease. Restoration of TCR signals to normal upon increased signaling through a TFF raises hope for a new avenue of treating systemic autoimmune diseases.

Involvement of CD8⁺ T Cells in the Pathogenesis of Giant Cell Arteritis and Polymyalgia Rheumatica. Maxime Samson¹, Sylvain Audia², M. Alika Trad¹, Marion Ciudad³, Hervé Devilliers¹, Alexandre Gautheron², Valérie Quipourt¹, François Maurier¹, Nadine Mœaux Ruault¹, Patrick Manckoundia¹, Paul Ornetti¹, Jean-François Maillefer³, Jean-François Besancenot¹, Christophe Ferrand³, Philippe Saïs³, Laurent Martin⁴, Nona Jankishvili⁵, and Bernard Bonnotte⁶. ¹INSERM UMR 1098, Besançon ; ²University of Burgundy, Faculty of Medicine, IFR100 ; ³Department of Internal Medicine and Clinical Immunology, Dijon, France; ⁴INSERM UMR 1098, Besançon, Dijon, France; ⁵Department of internal medicine and systemic diseases, Dijon, France; ⁶Department of Geriatric Internal Medicine, Dijon, France.

Background/Purpose: Previous studies have demonstrated the implication of CD4⁺ T cells, especially T helper (Th1) and Th17 cells, in the pathogenesis of giant cell arteritis (GCA) and polymyalgia rheumatica (PMR). However, very little is known concerning CD8⁺ T cells. This study aimed to investigate their implication in the pathogenesis of GCA and PMR.

Methods: Thirty patients suffering from GCA (n = 23) or PMR (n = 7) and 21 age-matched healthy volunteers were enrolled. Blood samples were collected at diagnosis and after 3 months of glucocorticoid (GC) treatment. Percentages of circulating cytotoxic T lymphocytes (CTL) (CD3⁺CD8⁺ Perforin⁺ GranzymeB⁺), Tc1 cells (CD3⁺CD8⁺ IFN-γ⁺), Tc17 cells (CD3⁺CD8⁺ IL-17⁺) and the expression of CXCL9, HLA-D, CR5, CR6, CR7, CD26L and CXCR3 by CD8⁺ T cells of GCA and PMR patients were determined by flow cytometry analysis. Levels of soluble Granzyme A, Granzyme B, CCL2, CCL20, CCL9, CXCL10 and CXCL11 were determined by ELISA or LumineX® technology. Temporal artery biopsies (TAB) were stained for CD3, CD4, and CD8. Data are expressed by mean±SEM and P value is the result of the Mann Whitney U test or Wilcoxon matched-pairs signed rank test, when appropriate.

Results: Percentages of circulating CTL and Tc17 in total CD8⁺ T cells were significantly higher in controls: 36.6±4.1% vs. 16.3±3.1% (P = 0.0004) and 5.9±0.11 vs. 0.15±0.03% (P < 0.0001), respectively. The level of Tc1 cells was not different between two groups. CD63 expression, which is expressed at the membrane once CTL have degranulated, was higher in patients than in controls (29.3±3.5 vs. 14.8±2.9%; P = 0.003). Levels of Granzyme A and B were also significantly increased in the serum of patients when compared to controls: 20.6±4.4 vs. 11.6±2.7 µg/mL (P = 0.02) and 3.2±1.3 vs. 0.95±0.49 µg/mL (P = 0.044), respectively. After 3 months of GC treatment, percentages of circulating CTL and Tc17 and soluble levels of Granzyme A and B were significantly decreased, whereas the percentages of Tc1 and CD3⁺CD8⁺ cells in total CD8⁺ T lymphocytes remained stable. Expression of chemokine receptors was comparable between patients and controls except for CXCR3 that was expressed at a higher level by CD8⁺ T cells from patients: 48.1±3.6 vs. 28.5±3.5% (P = 0.0004). Levels of CXCR3 ligands were increased in the serum of patients compared to controls: 629.8±194.7 vs. 92.8±132.2 pg/mL (P = 0.0001) for CXCL9, 31.4±6.9 vs. 9.2±1.5 pg/mL (P = 0.0001) for CXCL10 and 120.±0.1 vs. 35.7±2.7 pg/mL (P = 0.009) for CXCL11. Importantly, the levels of these 3 chemokines were decreased after 3 months of GC treatment. Immunohistochemical analyses of TAB (5 GCA patients) revealed a strong infiltration by CD4⁺ and CD8⁺ T cells in all the layers of the artery.

Conclusion: This study provides the first data that demonstrate an implication of CD8⁺ T cells in the pathogenesis of GCA and PMR. In untreated patients, CD8⁺ T cells, that infiltrate lesions of vasculitides, have an activated phenotype that is partly corrected by GC treatment. CXCR3 is upregulated on CD8⁺ T cells from GCA and PMR patients while levels of CCL9, -10 and -11 are increased in the serum of patients, which argues for the implication of CXCR3 in the homing of CD8⁺ T cells in the lesions of GCA.

Background/Purpose: Patients with age-related macular degeneration (AMD), a leading cause of irreversible blindness, have a 10-fold increased prevalence of abdominal aortic aneurysms. Single nucleotide polymorphisms (SNPs) in a number of genes, including Complement Factor H (CFH) on chromosome 1 and age-related macular susceptibility protein 2 (ARMS2) and HTRA Serine Peptidase 1 (HTRA1) on chromosome 10, are strongly associated with increased risk for developing AMD. These AMD-associated loci are also strongly associated with vasculopathies, including choroidal neovascularization, EGPA, and Takayasu’s arteritis. The aim of this study was to test the hypothesis that AMD-associated gene variants may also be involved in the development of vasculitis, especially the large-vessel vasculitides (LVV) and Takayasu’s arteritis (TAK).

Methods: A candidate gene study was performed to investigate the association between variants in AMD and LVV (TAK) gene. In these subjects, presence of the killing activity was determined for 1799 of the controls and 1710 of the cases. In these subjects, presence of the killing activity was determined for 1799 of the controls and 1710 of the cases. The study included patients with LVV and 1248 healthy controls matched for age, sex, race, and ethnicity. Additive p-values were calculated for each subtype of vasculitis.

Results: The main results of the study are reported in the Table. The controls had a minor allele frequency (MAF) of 21% for rs10490924. Overall, there was a significant association of all vasculitis types with rs10490924.

Conclusion: This candidate gene study demonstrated a significant association between variants in ARMS2 and idiopathic forms of vasculitis, including large-vessel vasculitides. Further validation is needed, this study suggests the possibility of a common pathogenesis between arteriopathology in AMD and large-vessel vasculitis.

Association of rs10490924 with Vasculitis

2852 Evaluation of KIR3DL1/KIR3DS1 Association with Behcet’s Disease in Turkish Individuals.

Background/Purpose: Behcet’s disease (BD)-associated HLA-B type, HLA-B*51 (B*51), is a ligand for a pair of allotype killer immunoglobulin-like receptors (KIR) present on cytotoxic cells — KIR3DL1, which inhibits their cytotoxicity, and KIR3DS1, which activates their cytotoxic activity. KIRs are inherited in evolutionarily conserved haplotypes in which KIR3DL1 and KIR3DS1 are mutually exclusive. We therefore tested the hypothesis that KIR-regulated cytotoxic mechanisms contribute to BD by testing for association between the presence of KIR3DL1 and KIR3DS1 alleles in Turkish individuals.

Methods: Turkish BD patients (n = 1,900) and controls (n = 1,779) were genotyped for the KIR3DL1 and KIR3DS1 alleles with two sequence-specific PCR assays. Genotypes of 6,994 SNPs from the HLA region were determined with the Illumina bead array and used to impute the individuals’ HLA types using SNP2HLA and a reference panel of 5,225 European individuals. A chi-squared test for association was used to evaluate the contribution of KIR3DL1 and KIR3DS1 to BD. A P-value less than 0.05 was considered significant.

Results: Classical HLA types were determined by imputation in all samples and types with posterior probability greater than 0.9 were included in analyses. KIR3DL1 and KIR3DS1 genotypes were determined for 1799 of the controls and 1710 of the cases. In these subjects, presence of the killing activity was determined for 1799 of the controls and 1710 of the cases. The activating allele did not appear to interact with HLA-B alleles. It was present at similar frequencies in B*51-positive cases and controls (43.0% vs 43.0%, P = 0.63), in Bw4-positive cases and controls (43.0% vs 41.1%, P = 0.31), and in cases and controls bearing the Bw4 motif with isoleucine at position 80 (43.7% vs 41.4%, P = 0.32). Similarly, no disease association was found for the inhibitory KIR3DL1 allele in all the samples or any in the HLA-B subsets.

Conclusion: We found no association of BD with the presence of the KIR3D activating (KIR3DS1) or inhibitory (KIR3DL1) receptors, which together regulate cytotoxic cell activity through binding of a subset of HLA class I molecules, including the BD-associated HLA-B*51. Due to the complexity of this locus (i.e., sequence variation, copy number variation), lack of association between BD and the presence/absence of KIR3DS1 or KIR3DL1 does not exclude a role for KIRs in the pathogenesis of BD. Further studies of KIR3DL1/KIR3DS1 types and copy number variants, as well as other KIRs, are warranted.

2853 Comparative Study of Inflimab Versus Adalimumab in Patients with Refractory Uveitis Due to Behcet’s Disease. Multicenter Study of 125 Cases.

Results:

- Inflimab was well tolerated by all patients.
- Adalimumab was well tolerated by all patients.

Conclusion: The study found no significant difference between the two treatments in terms of efficacy and safety.
1 year of therapy ADA and IFX do not show differences in the visual outcome of patients with refractory ulcers due to BD.

Conclusion: After 1 year of therapy ADA and IFX do not show differences in the visual outcome of patients with refractory ulcers due to BD.

Effect of Apremilast on Quality of Life and Physical Function in Patients with Behcet's Syndrome. Gulen Hatemi1, Melike Melikoglu2, Recep Tunc2, Cengiz Korkmaz2, Barun Turgit Ozturk2, Cem Mat2, Peter A. Merkel2, Kenneth Calamia2, Lilia Pineda3, Ziqi Liu4, Randall M. Stevens5, Hasim Y azici6 and Yusuf Y azici6.

Wednesday, November 18

Background/Purpose: The oral ulcers in Behcet's syndrome (BS) can be painful, causing difficulty in eating and speaking, and can impair the quality of life. Apremilast is an oral phosphodiesterase 4 inhibitor that modulates inflammatory pathways. A clinical trial demonstrated a beneficial effect on oral ulcers with this agent. For this study, we aimed to assess whether apremilast is effective in improving quality of life in patients with BS.

Methods: This was a phase 2, multicenter, controlled study of 111 patients with BS, without major organ involvement but with ≥2 oral ulcers, who were randomized to apremilast 30 mg BID or placebo for 12 weeks, followed by a 12-week active-treatment period for all patients. The primary outcome, which was the number of oral ulcers at Week 12, and secondary outcomes at Week 12, including oral ulcer pain, number of genital ulcers, number of patients with a complete or partial response, number of genital ulcers, and disease activity assessed by the BS activity scale (BAS) and Behcet’s disease current activity form, have already been reported. We now report the results of health related quality of life measurements from the trial (using the BSQoL questionnaire). We used the BSQoL questionnaire and the SF-36v2 questionnaire to assess quality of life at baseline and at Week 12.

Results: The mean ± SD BASQoL score showed a significantly greater improvement from baseline at Week 12 with apremilast vs. placebo (4.5 ± 7.61 vs. –1.6 ± 5.30; p = 0.0397). The mean ± SD SF-36v2 physical

Efficacy and Safety of Rituximab Retreatment Regimen at Clinical Relapse in Severe Cryoglobulinemic Vasculitis. Luca Quaruccio1, Francesca Zuliani2, Patrizia Scaini1, Marco Lenzi1, Antonio Tavoni1, Marco Sebastiani1, Teresa Urraro1, Francesco Saccardo1, Costanza Sbrigella2, Pietro Pioletti1, Paolo Fraticelli1, Davide Filippini1, Salvatore Scarpato1, Onesti Perrella1, Armando Gabrielli14, Dario Roccatello15, Anna Linda Zignego2, Clodoveo Feri2, Stefano Bombardieri7, Maurizio Pietrogrande8, Massimo Gali3, Giuseppe Monti9 and Salvatore De Vita10.

Background/Purpose: Two independent controlled randomized trials recently reported the efficacy and safety of rituximab (RTX) monotherapy in severe cryoglobulinemic vasculitis (CV) (1, 2), with one reporting a follow-up lasting two years (1). The aim of this study is to report the very long term efficacy and safety of a retreatment regimen with RTX administered at clinical relapse after the end of the abovementioned trial (1).

Methods: Long term follow up data of a trial of RTX in severe CV (1) were analysed, by considering patients managed with retreatment with RTX at clinical relapse. During this follow-up, only RTX monotherapy was used. Number of retreatments, disease activity at last follow up, adverse events and causes of deaths were registered. Clinical response was evaluated at the last follow-up visit, as follows: i) complete response (remission), partial response (response < 50% of at least one manifestation among glomerulonephritis, severe neuropathy or skin ulcers) (1), and active disease despite treatment.

Results: After the end of the 24-month controlled trial (1), follow-up data were analysed in 30 patients, all positive for hepatitis C virus infection. The mean follow up after beginning of RTX therapy (1) was 72.6±20.4 months, including 24 (80%) patients followed for more than 4 years and 6 (20%) patients followed for 2.4–4 years. Of them, 21 patients were still under an active follow up, 3 patients were lost from follow-up shortly after the end of the trial, and 6 patients died. Survival of RTX regimen was 7.6±0.3 yrs (mean±standard error). Seventeen out of 30 (56.7%) patients needed a retreatment for relapse of their disease after 6 months. 6/30 were retreated during the first 9 months only after the end of the trial and 1/30 during both follow-up periods, accounting for 25 retreatments in total, the first one at a mean of 22.3±12.1 months from last RTX cycle during the trial. Patients were retreated for nephritis (7/25), neuropathy (12/25), skin ulcers (6/25) or widespread purpura (6/25). Of the 17 patients retreated, 6/17 (35.3%) showed complete response at the last follow-up, 5/17 (29.4%) a partial response, while 6/17 (35.3%) had an active disease. Interestingly, of the remaining 13/30 patients undergoing only one single course of RTX during the follow-up, 6/13 were still in active follow-up and in clinical remission at the last follow-up. Recurrent infections occurred in three patients (10%; urinary and upper respiratory), related to severe hypogammaglobulinemia (IgG < 3 g/l) in 2/3. Death occurred in 6 patients. However, only 2/6 deaths were linked to relapsed vasculitis, with new onset of intestinal vasculitis.

Conclusion: A long-term RTX monotherapy with a retreatment at relapse regimen is effective and safe in cryoglobulinemic vasculitis, with low rate of severe hypogammaglobulinemia. Clinicians should be aware to promptly recognize and treat clinical relapse, as well as concomitant infections. Relapses with life-threatening manifestations (i.e. intestinal vasculitis) were uncommon. Further investigation may be required to select patients where maintenance RTX therapy may be the best choice.

Restricting Back Pain Is Strongly Associated with Disability in Community-Living Older Persons over the Course of 13 Years. Una Makris, Lisa Fraenkel, Ling Han, Linda Leo-Summers and Thomas M. Gill. 1Department of Medicine, University of California, Los Angeles, CA; 2Department of Medicine, New Haven, CT, 3Department of Medicine, New Haven, CT, 4Yale University, New Haven, CT.

Background/Purpose: Although back pain is common and costly, few longitudinal studies have evaluated the association between back pain severe enough to restrict activity and the development of disability. The objective of this study is to evaluate the association between RBP and subsequent episodes of disability in basic, instrumental, and mobility activities, respectively.

Methods: Participants included the 754 members of the Precipitating Events Project (median age 78 y, 64.6% women), a prospective study of community-living persons, aged 70+ years, who completed monthly telephone assessments of RBP and disability, and who were at risk for developing new and recurrent disability episodes for up to 159 months. RBP was defined as staying in bed for at least 1/2 day and/or cutting down on one's usual activities due to back pain. Disability was defined as needing help with/inability to complete ≥1 of the activities, listed in the Table, in any given month for each of the three outcome categories. The event rates for the three disability outcomes were estimated using a GEE Poisson model. A recurrent events Cox model was used to evaluate the association between RBP and each of the three disability outcomes. The model was adjusted for fixed-in-time (sex, education, ethnicity) and time-varying covariates (listed in Table) (age, chronic conditions, BMI, depressive symptoms, cognitive impairment, physical frailty) that were updated every 18 months.

Results: For the basic, instrumental and mobility activities, the disability event rates were: 3.6 per 100-person months (95% CI 3.37, 3.89), 8.5 per 100-person months (95% CI 8.05, 8.98), and 9.38 per 100-person months (95% CI 8.98, 9.81), respectively, with a median duration of 2 months per disability episode for each of the three outcomes. The unadjusted and adjusted associations of restricting back pain with the 3 disability outcomes are listed in the Table.

Conclusion: In this longitudinal study, RBP was independently associated with disability in basic, instrumental and mobility activities among older persons. Interventions directed at preventing or decreasing RBP may reduce the likelihood of disability in activities across three key domains of function.

Randomized Controlled Trial of Postoperative Care Navigation in Total Knee Arthroplasty Patients: Does One Size Fit All? Elena Losina, Jamie E. Collins, John Wright, Meghan E. Daigle, Laurel Donnell-Fink, Doris Strnad, Vladislav Lerner, Stanley Abrams and Jeffrey N. Katz. Brigham and Women’s Hospital, Boston, MA.

Background/Purpose: A number of TKA recipients have suboptimal improvements after surgery. Our objective was to establish the efficacy of a motivational-interviewing (M)-based telephone intervention aimed at improving functional outcomes post-TKA and to identify subgroups especially likely (or unlikely) to benefit from the intervention.

Methods: We conducted the RCT to compare functional status in TKA recipients randomized to one of two strategies: 1) enhanced postoperative care with frequent follow-up by a care navigator; 2) usual postoperative care. Those who were randomized into the care navigation arm received ten calls from a trained non-clinician care navigator over the first 6 months post-TKA. The trained navigator used theory-driven M to engage TKA recipients in discussions about their rehabilitation goals, including plans for confidence in achieving those goals. Patients in the usual care arm received standard postoperative care. Patients in both arms were assessed at baseline, 3 and 6 months post-TKA. The study enrolled subjects 40+ years of age with OA who were scheduled for TKA. Primary outcome was the difference between the arms in WOMAC function score change, over the 6 months post-TKA.
We defined a satisfactory functional improvement as either achieving WOMAC function scores $< 15$ or reducing pre-operative functional score by $19$+ points, suggested as MCID in TKA patients (Escobar, 2007). We examined whether sex, obesity and pain catastrophizing affected the efficacy of the care navigator intervention.

**Results:** We enrolled 309 TKA recipients, average age 67 years; 60% female. 84% Kelgren-Lawrence Grade 4, 50% obese (BMI $> 30$ kg/m$^2$). Mean pre-operative WOMAC function score was $40$ (18), on a 0-100 scale; 100-worst. Baseline characteristics did not differ between study arms. At 6 months, participants in care navigation arm improved by 29.4 (16.1) points compared to 26.1 (18.3) in control arm ($p = 0.1126$). Overall, 21% of study participants did not achieve satisfactory functional improvements, with similar rates across arms. Greater pain catastrophizing led to less improvement over and its association with poor outcome was more prominent among females compared to males ($p$ value for interaction $= 0.0022$). Further analysis revealed that females showed that greater pain catastrophizing modified the impact of the intervention: females with a low degree of pain catastrophizing improved by 8 points more (33 vs. 25) in the navigation arm than in the control arm, while females with a high degree of pain catastrophizing improved by five points less in the navigation arm than in the control arm ($p$-value for interaction $= 0.0233$).

**Conclusion:** The results of this RCT did not show benefits of the MI based enhanced postoperative care navigation in functional improvements in TKA recipients. The negative overall result could be explained by differential effect of intervention among females with high and low levels of pain catastrophizing. Greater focus on understanding the determinants of and effective therapies for reducing pain catastrophizing could improve the efficacy of interventions focused on better functional outcomes in TKA recipients.

**Randomised Comparison of the Effectiveness of a Non-Pharmacological Multidisciplinary Face-to-Face Group-Based Treatment Program Vs a Telephone-Delivered Treatment Program on Knee Function in Patients with Generalized Osteoarthritis.** Nienke Cuperus$^1$, Thomas Hoogeboom$^2$, Clarinda Kersten$^3$, Leonie Rietveld$^4$, Aïfons den Broeder$^5$, Thea Vliet Vlieland$^6$ and Cornelia H.M. van den Ende$^6$. 1Sint Maartenskliniek, Nijmegen, Netherlands, 2CAPRI school for public health and primary care, CCTR centre for Care Technology Research, Maastricht University, Maastricht, Netherlands, 3Leiden University Medical Center, Leiden, Netherlands.

**Background/Purpose:** Generalized osteoarthritis (GOA) is a widely accepted and prevalent OA phenotype characterized by the involvement of multiple joints. However, current research and clinical practice mostly examine OA populations for a specific OA localization. The effectiveness of non-pharmacological interventions for GOA is therefore largely unknown. In addition, there is no evidence concerning the optimal mode of care delivery. Therefore, we compared the effectiveness of a non-pharmacological multidisciplinary face-to-face group-based treatment program versus a telephone-delivered treatment program on daily function for patients with GOA, until one year after treatment.

**Methods:** In this single blind randomized clinical superiority trial, individuals clinically diagnosed with GOA were randomly allocated to either a six week multidisciplinary face-to-face group-based treatment program or a six week telephone-delivered treatment program. Both programs aimed to improve daily function and to enhance self-efficacy to control the disease. The programs had comparable content but critically differed in mode of delivery and intensity. Primary (daily functioning; HAQ-DI) and secondary outcome measures were assessed at baseline, 6, 26 and 52 weeks. The 6-week time point was used to assess the short-term effects of both interventions. The average score obtained from the 6, 26 and 52 time points was used to assess the long-term effects. Directly after finishing the treatment patient satisfaction was measured. Multiple imputation was used to estimate missing values. Differences in effectiveness between both treatment programs were analysed using linear regressions adjusted for baseline, sex and age.

**Results:** Of 158 randomized patients (mean (SD) age 60 (8); female 85%), 147 (93%) completed at least the baseline measurement and were included in the intention to treat analysis. Of these patients, 75 were allocated to the face-to-face-treatment program and 72 to the telephone-delivered treatment program. No difference in effectiveness between both treatment groups was found on the HAQ-DI at both the short (p = 0.59) and long-term (p = 0.65). Moreover, no differences in effectiveness between the two modes of care delivery on the secondary outcomes were found (p > 0.05). Patient satisfaction was significantly higher in the face-to-face treatment program than in the telephone-delivered treatment program.

**Conclusion:** In this trial we found no differences in effectiveness between two modes of delivery of non-pharmacological care for patients with GOA. Therefore, our results imply that the choice of mode of treatment delivery i.e. face-to-face versus telephone-delivered could be based on patients’ preferences and/or costs.

**Changes in Knee Kinematics from a 6-Week Hip and Trunk Strengthening Program for Persons with Patellofemoral Osteoarthritis.** Lisa Hoglund$^1$, Laura Pontiggia$^1$, John Kelly IV$^2$, Mark Arnott$^1$, Olumide Babalola$^1$, Andrew Gushen$^1$ and James Carey$^1$. 1University of the Sciences, Philadelphia, PA, 2University of Pennsylvania, Philadelphia, PA.

**Background/Purpose:** Patellofemoral (PF) osteoarthritis (OA) is prevalent in middle-aged adults. Ablation lower extremity (LE) biomechanics is one etiology of knee OA. Reduced peak knee flexion angles and increased peak tibial abduction angles were reported during sit-to-stand (STS) in persons with general knee OA and with PF OA, respectively. Additionally, reduced strength of the hip abductor, hip extensor, and knee extensor muscles was reported in PF OA, which may impact LE biomechanics. Studies have reported improved knee and hip biomechanics in persons with PF pain when treated with proximal LE strengthening. It is unknown if a proximal LE strengthening program with pelvic/abdominal stabilization training will alter LE kinematics, improve symptoms, and improve function in persons with PF OA. This study examined the impact of a 6-week hip and trunk muscle strengthening and stabilization program on knee and hip kinematics during STS and a step-down (SDn) task and self-reported symptoms and function in persons with PF OA.

**Methods:** Six female subjects with PF OA and anterior knee pain, median age (interquartile range [IQR]): 52 years (48-56 years) participated in the study. Subjects attended a biomechanical evaluation, 10 supervised exercise treatment sessions, and a reevaluation. Biomechanics of the most painful LE were examined during STS from a stool and SDn on a 3-step staircase. Subjects were treated with hip and abdominal/trunk strengthening exercises. In addition, subjects were instructed in proper LE position and pelvic stability. Outcome measures included triplanar knee and hip joint peak angles and the Knee Injury and Osteoarthritis Outcome Score (KOOS). Data analysis included group medians (IQR) and Wilcoxon Signed Rank tests.

**Results:** Peak knee flexion angle during STS increased: Initial: 76° (67, 86), Final: 93° (87, 97), $p = 0.03$. Peak knee extension angle during STS decreased: Initial: 2° (0.4, 9), Final: -7° (-11, -4), $p = 0.03$. Peak knee extension angle during SDn decreased: Initial: -0.2° (-5, 0.5), Final: -11° (-16, -6), $p = 0.03$. KOOS-Symptoms score improved: Initial: 62 (54, 68), Final: 75 (68, 89), $p = 0.03$. KOOS-Function score improved: Initial: 69 (47, 76), Final: 84 (79, 85), $p = 0.03$.

**Conclusion:** A hip and trunk strengthening program with education in proper LE alignment and pelvic stability resulted in increased knee flexion angles and reduced knee extension angles during two tasks that increase PF joint stress. In addition, subjects reported significant improvement in symptoms and function. The intervention may have improved subjects’ ability to tolerate loading the PF compartment in activities requiring knee flexion. This may be one method to improve symptoms and function in persons with PF OA.

**Satisfaction Following Total Knee Replacement: Journey or Destination?** Jeffrey N. Katz$^1$, Yian Dong$^1$, Jamie E. Collins$^1$, John Wright$^1$, David Dalury$^2$, Kirk Kinnsfater$^1$ and Elena Losina$^1$. 1Brigham and Women’s Hospital, Boston, MA, 2Townson Orthopedics, Maryland, Baltimore, MD, Orthopedic Center for the Rockies, Ft. Collins, CO.

**Background/Purpose:** Total knee replacement (TKR) outcome is often assessed with measures of pain and function (fxn), but there is no consensus on whether surgery should be evaluated as extent of improvement on these scores (“journey”) or final score (“destination”). We addressed this question.
by evaluating whether improvement (journey) or final score (destination) is more closely associated with patient satisfaction with TKR.

Methods: We analyzed data from a prospective, multicenter cohort undergoing TKR. Subjects completed the WOMAC Pain and Fxn scales (0–100, 100 worst) preoperatively and 6 months postoperatively. At 6 months patients also completed a question on satisfaction with results of TKR. We defined the journey criterion as improvement by the minimal clinically important difference following TKR, ≥23 points on the WOMAC Pain or ≥31 on WOMAC Fxn Scale (Escobar et al). The destination criterion was the Patient Acceptable Symptom State following TKR, <31 on WOMAC Fxn (Tubach et al). We calculated the number of subjects who achieved the journey criterion, the destination criterion, both or neither. In each group, we calculated the proportion who reported being dissatisfied, somewhat satisfied and very satisfied with surgery. We used ordinal logistic regression to examine independent effects of achieving journey or of achieving destination criteria on satisfaction with TKR.

Results: 329 subjects were included, mean age 66, 57% female. Mean preoperative WOMAC Pain and Fxn scores were 40 (sd 18) and 42 (sd 17) respectively. 238 subjects (72%) met both journey and destination criteria for success while 10 (3%) met neither criterion. 63 subjects (19%) achieved the destination criterion but not journey, while 18 patients (5%) achieved the journey criterion but not destination. Among subjects who achieved the destination but not the journey criterion, 59% were satisfied and only 6% were dissatisfied (Figure). Among those who achieved the journey but not the destination criteria, 44% were very satisfied and 33% were dissatisfied. In ordinal logistic regression models that adjusted for age, sex and baseline WOMAC Fxn, achieving the destination criterion had a stronger association with satisfaction (OR 7.7, 95% CI 3.2, 18) than the journey (OR 2.2, 95% CI 1.0, 4.7). This finding was essentially unchanged when we excluded the 30 subjects with preoperative WOMAC Fxn scores < 19, who were not eligible to achieve the journey criterion.

Conclusion: Improvement in outcome score (journey) and final score (destination) are distinct metrics for assessing results of surgery. In this TKR cohort, both metrics were associated with patient satisfaction with the results of TKR, with destination having a stronger association than journey. These data suggest that both journey and destination criteria should be integrated into patient-centered assessment of TKR.

**Methods:** This study comprised 411 patients with autoimmune diseases who visited Hokkaido University Hospital Rheumatology Clinic between 2002 and 2003. Demographic, clinical data and cardiovascular risk factors were obtained from the medical charts. Lupus anticoagulant (LAC) assays and IgG/M anticardiolipin antibodies, IgG/M anti-β2-glycoprotein I antibodies and IgG/M phosphatidylserine dependent anti-thrombin antibodies were performed in all subjects. Among all the patients, 257 (62.5%) patients with follow-up period of more than 5 years (median follow-up periods: 126(IQR 92.5,33) months) were eligible. The demographic and clinical characteristics of these patients are as follows: 17(7%) primary APS, 25(10%) APS with systemic lupus erythematosus(SLE), 84(33%) SLE (without APS), 45(18%) rheumatoid arthritis and 85 patients with other autoimmune diseases.

To evaluate the diagnostic powers for GAPPS and aPL-S, area under the curve (AUC) of receiver operating characteristic (ROC) curves were calculated. To evaluate the powers of the two scores for thrombosis prediction, Cox proportional hazard regression analyses were performed separately for each score with the cut off derived on the ROC curve. Each risk factor for the multivariate Cox analyses were assessed through separate univariate Cox regression test. To evaluate and compare the predictive powers of the two scores, Somer’s d coefficient was calculated.

**Results:** Thirty-seven patients newly developed thrombosis during the observation period; 23 arterial thrombosis and 23 venous thrombosis. The ROC curve of GAPPS showed higher AUC than that of aPL-S (0.693 vs 0.656, p<0.05) indicating that GAPPS have better ability of diagnosing APS (GAPPS vs aPL-S: 0.693 vs 0.656, p<0.05 ). The cut off values of GAPPS and aPL-S for predicting future thrombosis were 10 and 31, respectively. The Cox multivariate proportional hazard regression analyses revealed that both scores, with appropriate cut off levels, accurately reflected the risks of future thrombosis with statistic significance (GAPPS – 10 p=0.01, aPL-S – 31 p=0.0001). The aPL-S showed higher Somer’s d coefficient than GAPPS (0.497 vs 0.412, respectively, p<0.05).

**Conclusion:** The aPL-S and GAPPS accurately reflected the diagnosis of APS and the risk for future thrombotic events in patients with autoimmune diseases in our cohort. GAPPS may have relatively high potential for APS diagnosis and aPL-S might be superior to GAPPS in predicting future thrombosis.

**External Validation of the Global Anti-Phospholipid Syndrome Score in Comparison to IgG Antibodies Directed Against Domain I of β2-Glycoprotein I. A Prospective Multicentre Cohort Study.**

**Background/Purpose:** The aim of this study was to externally validate the GAPPS score against other IgG antibodies directed against Domain I of β2-Glycoprotein I (aPL-I). To this end, we performed a prospective multicentre cohort study of patients with APS.

**Methods:** A total of 411 patients with APS were recruited from 12 centres in 9 European countries. Inclusion criteria were: clinical APS according to ACR criteria, presence of lupus anticoagulant (LA), or aPL-I in patients with APS. Exclusion criteria were: patients with systemic lupus erythematosus (SLE), or rheumatoid arthritis. The score was validated in the external cohort; 176 patients (43%) with APS and 235 control patients (57%). The primary outcome was the occurrence of a primary APS-related event. Patients were followed up for a median of 5 years (interquartile range 4-6 years).

**Results:** Of the 411 patients, 176 (43%) were included in the external validation cohort. The external validation cohort was similar to the development cohort with respect to several clinical characteristics, except that the proportion of women was lower in the external validation cohort. The externally validated GAPPS score had a strong predictive value for APS-related events (area under the ROC curve = 0.79, 95% confidence interval 0.74-0.84). The discriminatory power of the GAPPS score was similar to that of the aPL-I titre (area under the ROC curve = 0.76, 95% confidence interval 0.71-0.81). The externally validated GAPPS score remained a strong predictor of APS-related events after adjusting for age, sex, and cardiovascular risk factors (hazard ratio 1.04 per 1 point increase in GAPPS score, 95% confidence interval 1.02-1.06, p=0.003). The externally validated GAPPS score was highly predictive of both arterial and venous APS-related events (arterial: area under the ROC curve = 0.71, 95% confidence interval 0.64-0.79, p=0.007; venous: area under the ROC curve = 0.78, 95% confidence interval 0.71-0.85, p<0.001).

**Conclusion:** The externally validated GAPPS score was highly predictive of both arterial and venous APS-related events. The externally validated GAPPS score remained a strong predictor of APS-related events after adjusting for age, sex, and cardiovascular risk factors. The externally validated GAPPS score was highly predictive of both arterial and venous APS-related events. The externally validated GAPPS score remained a strong predictor of APS-related events after adjusting for age, sex, and cardiovascular risk factors.

**Disclosures:** B. Artim-Esen: None; N. Smoktunowicz: None; V. M. Ripoll: None; C. Pericles: None; R. Chambers: None; I. Mackie: None; D. Isenberg: None; A. Rahman: None; Y. Ioannou: None; I. Giles: None.
anticardiolipin and anti-\(\beta_2\)-glycoprotein I antibodies). GAPPS was computed for each patient.

**Results:** One hundred and thirty eight patients (median age 43.5±15.3 years; 108 women) were followed-up for a mean duration of 43±20.7 months (493.9 patient-years). Thrombosis during follow-up occurred in 16 patients (3 strokes, 1 myocardial infarction, 1 splanchic arterial thrombosis, 3 pulmonary embolisms, 3 deep veins, 5 small vessels thromboses). Higher values of GAPPS were seen in patients who experienced thrombosis compared to those without (10.9±4.8 vs 7.9±5.4, p=0.03). While triple positivity (HR = 3.38 [CI95%; 0.83–6.80], p=0.01) and GAPPS above 10 (HR = 1.56 [CI95%; 0.55–4.47], p=0.41) were not predictive of further incident thrombotic events, GAPPS above 16 (HR = 5.27 [CI95%; 1.16–23.39], p=0.03) and high levels of antiDI above the 90th percentile of patients (HR = 0.55–4.47, p=0.014) were highly predictive of incident thrombotic events.

**Conclusion:** GAPPS and high levels of antiDI are significant predictors of thrombosis in aPL/SLE patients. These antibodies seem to add a substantial improvement in risk prediction of thrombosis independently of clinical variables assessed by GAPPS’ components.

**Antiphospholipid Antibodies Promote the Release of Neutrophil Extracellular Traps: a New Mechanism of Thrombosis in the Antiphospholipid Syndrome**

Srikanthi Yalavarthi1, Levi F. Maza2, Alexandra E. Morris3, Carlos Nuñez-Alvare3, Diego Hernández1, Paula B. Bockenstedt1, Antonio R. Cabr5, and Jason S. Knight1. 1University of Michigan, Ann Arbor, MI, 2Hospital de Estado do Rio de Janeiro, Rio de Janeiro, Brazil, 3APS ACTION, New York, NY.

**Background/Purpose:** Antiphospholipid antibodies (aPL), especially those targeting beta-2-glycoprotein I, are known to activate endothelial cells, monocytes, and platelets, with prothrombotic implications. However, the interaction of aPL with neutrophils and leukocyte in human blood, the neutrophil, has only rarely been considered. Neutrophil extracellular trap (NET) release—a form of neutrophil cell death that results in the externalization of decondensed chromatin decorated with granular proteins—has recently been recognized as an important activator of the coagulation cascade, as well as an integral component of deep vein thrombi in both humans and animals. Here, we hypothesized that aPL activate neutrophils to release NETs, thereby predisposing to thrombosis.

**Methods:** Neutrophils, sera, and plasma were prepared from patients meeting criteria for primary antiphospholipid syndrome (APS) by the revised Sapporo classification criteria (n=50), or from healthy volunteers. Circulating NETs were quantified in sera and plasma by a myeloperoxidase-DNA quantification assay. NETs from aPL-positive patients were scored for their ability to release NETs by both immunofluorescence microscopy and fluorescence-based quantification of extracellular DNA. Neutrophils from healthy volunteers were stimulated with APS patient sera, purified IgG, or aPL monoclonal antibodies, and NET release was quantified; dependence on generation of reactive oxygen species was also determined. Expression of known aPL receptors, beta-2-glycoprotein I and annexin A2, was measured on the neutrophil surface.

**Results:** Sera and plasma from APS patients have elevated levels of NETs as compared to healthy volunteers (2.7-fold increase when comparing means; p=0.0279). Neutrophils isolated from patients with primary APS are predisposed to spontaneous NET release when compared to healthy volunteers (p=0.0143). Importantly, APS-patient sera and IgG purified from patients with aPL, stimulate NET release from healthy-volunteer neutrophils (p=0.004 and 0.0187, respectively). Human aPL monoclonal antibodies, especially those that target beta-2-glycoprotein I, also enhance NET release; this enhancement can be abrogated by blockade of reactive oxygen species production (histologically and/or at registry entry) as well as the association between the aPL-related events and the aPL profile (triple, double, or single positivity based on inclusion tests). The results did not change when the single aPL group was restricted to LA-positive patients only (data not shown). The percentages of patients tested for aPL, aCL, and a2GPI were 93%, 100%, and 76%, respectively in the double aPL-positive group; 97%, 99%, and 77% in the single aPL-positive group. The percentages of the patients with positive LA, aCL, and a2GPI were 65%, 89%, and 39%, respectively in the double aPL-positive group; and 72%, 23%, and 5% in the single aPL-positive group.

**Conclusion:** Serum and plasma from patients with primary APS have more circulating NETs than healthy controls. Sera and plasma from APS patients have elevated levels of NETs as compared to healthy controls. Neutrophil netting warrants further investigation as a novel therapeutic target in APS patients.

**Antiphospholipid Syndrome Alliance for Clinical Trials and International Networking (APS ACTION)**

Doruk Erkan1, Daniela Andrade1, Maria Tektontidou1, Amaa Ugartec2, Alessandra Banzato3, Angela Tincani4, Pier-Lugi Morni2, Riccardo Ingegn4, Paul R. Fortin4, Roger A. Levy2, and On Behalf of APS Action. 1Hospital for Special Surgery, New York, NY, 2First Department of Internal Medicine, Laikon Hospital, Athens University Medical School, Athens, Greece, 3Hospital Universitario Cruces, Bizkaia, Spain, 4Department of Cardiac Thoracic and Vascular Sciences, University of Padua, Padua, Italy, 5Rheumatology and Clinical Immunology, Spedali Civili and University of Brescia, Brescia, Italy, 6University of Milan, Milano, Italy, 7Hospital Clinic, Barcelona, Spain, 8Laval University, Division of Rheumatology, Centre de Recherche du CHU de Quebec and Department of Medicine, Quebec City, QC, 9Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil, 10APS ACTION, New York, NY.

**Background/Purpose:** APS ACTION International Clinical Database and Repository (“Registry”) was created to study the natural course of disease over 10 years in persistently aPL-positive patients with/without other systemic autoimmune diseases. The objective of this preliminary analysis is to report the baseline characteristics of currently enrolled patients.

**Methods:** A secure web-based data capture system is used to store patient information including demographics, aPL/APS history, and aPL data. The inclusion criteria are positive lupus anticoagulant (LA) test based on the ISTH recommendations, medium-to-high titer (> 40U and/or > 99th percentile) anticardiolipin antibody (aCL) IgG/M/A, and/or medium-to-high titer anti-\(\beta_2\)-Glycoprotein-I (a2GPI) IgG/M/A tested at least twice within one year prior to enrollment. Clinical and blood collection (for core laboratory aPL confirmation and mechanistic studies) are performed once a year, or when patients develop new events. We used chi-square or Fisher’s exact test for group comparison, and linear-by-linear association test to analyze for trend.

**Results:** As of June 2014, 408 patients have been recruited from 17 centers globally (mean age at entry: 43.7±12.8y; female: 310 [76%]; white: 261 [69%]; and other systemic autoimmune diseases: 130 [32%]). Table shows the distribution of the aPL-related events (historically and/or at registry entry) as well as the association between the aPL-related events and the aPL profile (triple, double, or single positivity based on inclusion tests). The results did not change when the single aPL group was restricted to LA-positive patients only (data not shown). The percentages of patients tested for aPL, aCL, and a2GPI were 93%, 100%, and 76%, respectively in the double aPL-positive group; 97%, 99%, and 77% in the single aPL-positive group. The percentages of the patients with positive LA, aCL, and a2GPI were 65%, 89%, and 39%, respectively in the double aPL-positive group; and 72%, 23%, and 5% in the single aPL-positive group.

**Disclosures:** S. Yalavarthi, None; L. F. Maza, None; A. E. Morris, None; C. Nuñez-Alvarez, None; D. Hernández, None; P. L. Bockenstedt, None; A. R. Cabr6, None; J. S. Knight, None.

**Disclosure of Grants:** None; None; None; None.
Autoimmune Hemolytic Anemia (n:23) 9 (39%) 8 (35%) 6 (26%) 0.31
Cardiac Valve Disease* (n: 34) 18 (53%) 10 (29%) 6 (18%) 0.02
aPL-associated Nephropathy* (n:11) 2 (18%) 7 (64%) 2 (18%) 0.053
Skin Ulcers (n:21) 5 (24%) 8 (38%) 8 (38%) 0.58
Cognitive Dysfunction* (n: 10) 3 (30%) 4 (40%) 3 (30%) 0.27
MRI White Matter Changes (n:57) 18 (32%) 16 (28%) 23 (40%) 0.22

PEC: preeclampsia; EC: eclampsia; PI: placental insufficiency. * similar results with linear-by-linear association

**Conclusion:** Our preliminary analysis suggests that: a) there is no association between the aPL-related events and aPL profile (triple, double, or single positivity), except for Catastrophic APS and cardiac valve disease, based on a small number of patients; and b) LA positivity is the most important determinant of event risk in aPL-positive patients. Further analysis of the APS ACTION registry, i.e., detailed aCL/aPRo, GP1 titers, potential confounders, and core laboratory aPL profile, will clarify if triple, double, and single aPL profiles are associated with different risk profiles.

**TLR7 Influences Autoreactive B Cell Selection in the Germinal Center**
FKG, Institute of Medical Research, Malaysia.

**Background/Purpose:** TLR7 is required for the generation of anti-RNA antibodies and excess TLR7 confers a SLE-like phenotype in mice. Recent studies have shown that TLR7 expression in B cells is sufficient for this phenotype and that TLR7 excess enhances germinal center (GC) maturation. The goal of this study was to determine how TLR7 influences the GC derived autoreactive B cell repertoire.

**Methods:** TLR7 deficiency was crossed into NZW mice for 13 generations. The NZW/BKS.BY strain was used for NZW and NZW B6; TLR7+/−/B6, X.BYB/Yaa lupus prone mice. The Y.aa locus confers a partial deficiency for TLR7 in males and an accelerated lupus phenotype. NZW TLR7+/−/B6, X.BYB/Yaa mice were used, which carry only one copy of TLR7. To create a physiology setting in which autoreactive B cells compete for survival with non-autoreactive B cells, we generated 50% 3H9/50% wild type bone marrow chimeras in which transferred male 3H9. TLR7+/−/or TLR7+/− cells were GFP+ and can be easily identified. Mice were followed clinically and sacrificed at the onset of fixed proteinuria. Spleen cells were phenotyped and GC B cells were analyzed by single cell PCR for the repertoire of Vκ light chains associated with the 3H9 heavy chain. Full length Vκ5−43 encoded light chains were sequenced and their mutation frequency analyzed.

**Results:** Disease onset occurred with the same kinetics in TLR7+/−/and TLR7+/−/− chimeras and spleens from both sets of chimeras were phenotyped and sacrificed at the onset of fixed proteinuria. Spleen cells were phenotyped and GC B cells were analyzed by single cell PCR for the repertoire of Vκ light chains associated with the 3H9 heavy chain. Full length Vκ5−43 encoded light chains were sequenced and their mutation frequency analyzed.

**Conclusions:** Our results suggest that TLR7 influences proliferation autoreactive B cells into the GC, as well as their expansion and the frequency of somatic mutations. These effects of TLR7 are different from those in the Y.aa locus.

**B Cell-Intrinsic Deletion of the Type 1 Interferon Receptor Does Not Impact the Development of Murine Lupus**
W. S. Jackson, N. Bethune-ackian, N. Scharping, S. Khim and D. Rawlings.
Seattle Children’s Research Institute, Seattle, WA.

**Background/Purpose:** Type 1 interferon (IFN) is strongly implicated in lupus pathogenesis, and patients with SLE frequently express a ‘type 1 IFN gene signature’. Type 1 IFN promotes B cell activation in vitro suggesting a direct role for type 1 IFN in humoral autoimmunity. However, it is unclear whether type 1 IFN impacts lupus pathogenesis via B cell-intrinsic or –extrinsic mechanisms. We previously described the Wiskott Aldrich syndrome (WAS) model of B cell-driven autoimmunity (Becker-Herman et al., 2011; Jackson et al. 2014). An important advantage of the WAS chimeras is that dysregulated immune responses are limited to the B cell compartment, allowing genetic manipulation in a B cell-intrinsic fashion. In the current study, we describe the impact of B cell-intrinsic deletion of the type 1 interferon receptor (IFNα/IFNβ) in the WAS chimeras.

**Methods:** Proliferation of wild-type (WT), was−/−, ifnar−/− and double-deficient was−/−/ifnar−/− B cells was quantified after stimulation with LPS (TLR4 agonist), R848 (TLR7 agonist) and CPG (TLR9 agonist) −/−/IFN-β. To test the impact of B cell-intrinsic type 1 IFN activation in lupus pathogenesis we established bone marrow chimeras in which B cells were WT, was−/−, or was−/−/ifnar−/−; hereafter be referred to as BW, BW/IFNAR−/−, and BW/IFNAR−/−. Chimeras were analyzed for autoantibodies, immune activation and development of immune-complex glomerulonephritis by ELISA, flow cytometry and immunohistochemistry.

**Results:** We previously showed that autoimmunity in the WAS chimera model is dependent on B cell-intrinsic TLR7 activation (Jackson et al., 2014). Ifnar-deficient B cells demonstrated a specific defect in TLR7-induced proliferation, while TLR4 and TLR9 responses were unaffected. In addition, recombiant IFN-β enhanced TLR7 responses, without impacting TLR4/TLR9 activation. These data suggest a role of B cell-intrinsic type 1 IFN signals in lupus pathogenesis. To test this hypothesis, we generated chimeras with B cells double-deficient in was and ifnar. Surprisingly, although type 1 IFN promoted B cell TLR7 activation in vitro, autoantibodies to RNA-associated antigen smRNP were equivalent in BW, BW/IFNAR−/−, and BW/IFNAR−/− mice. Chimeras were analyzed for autoantibodies, immune activation and development of immune-complex glomerulonephritis by ELISA, flow cytometry and immunohistochemistry.

**Conclusions:** We previously showed that autoimmunity in the WAS chimera model is dependent on B cell-intrinsic TLR7 activation (Jackson et al., 2014). Ifnar-deficient B cells demonstrated a specific defect in TLR7-induced proliferation, while TLR4 and TLR9 responses were unaffected. In addition, recombinant IFN-β enhanced TLR7 responses, without impacting TLR4/TLR9 activation. These data suggest a role of B cell-intrinsic type 1 IFN signals in lupus pathogenesis. To test this hypothesis, we generated chimeras with B cells double-deficient in was and ifnar. Surprisingly, although type 1 IFN promoted B cell TLR7 activation in vitro, autoantibodies to RNA-associated antigen smRNP were equivalent in BW, BW/IFNAR−/−, and BW/IFNAR−/− mice. **Break of Anergy in Human Autoreactive B Cells By T Helper Signals Restores B Cell Receptor Signaling Capacity and Is Dependent on Upregulation of CD45 Phosphatase Activity-A Possible Novel Mechanism of B Cell Tolerance in Rheumatic Diseases**
Institute of Immunology, Rikshospitalet, Oslo University Hospital, Oslo, Norway, La Jolla Institute for Allergy and Immunology, La Jolla, CA.
**Results:** The dominant epitopes recognized by BDX2 autoAbs are those commonly found in human SLE patients. Many immunodominant epitopes are located in cryptic regions of the native protein. The strongest autoAb response was observed with nuclear peptides from RNA binding proteins (RBP) including lupus La, L23–27 LEAKICHQIEYYFGD, U1snRNP, 373 SHRSERERRRDARDRD, and SmD197–111 RGRGGGRGGRGGRGGRG. Other nuclear autoAbs include histones, centromere, and RNA polymerase III. Tetramer analysis revealed a significant expansion in La and snRNP memory B cells and marginal zone precursor (MZ-P) B cells in BXD2 vs. B6 in both the circulation and the spleen. Phenotype analysis of tetramer + MZ-P B cells showed upregulation of type I IFN inducible activation molecules CD69 and CD86 in BXD2 mouse spleens.

**Conclusion:** The bona fide presence of RBP cryptic autoAbs that were not predicted by Ag prediction programs is consistent with the finding that defective clearance of apoptotic blebs in BXD2 mice leads to production of autoAbs that break B cell tolerance. The potential activation of the TLR7 pathway by RPs in combination with the upregulation of type I IFN response in Ag-specific MZ-P B cells further suggests that expanded tetramer + MZ-P B cells may be a result of apoptotic cell clearance defects. In light of our previous findings that MZ-P B cells are exceptional apoptic Ag delivery to CD11c+ DCs, CD86+ cells and can stimulate CD4 T cells, these results suggest that specific targeting on TLR7 and type I IFNs may be important to eliminate autoreactive B cells.

**Epratuzumab Induces Broad Inhibition of B Cell Receptor Proximal Signaling but Has Opposing Effects on Distal Signaling in B Cell Subsets: A Profile of Effects on Functional Immune Signaling By Single Cell Network Profiling.** Alison Maloney1, Drew Holton1, Stephen Radecki2, Gianluca Fosseth3, Simon Lumb1, David Rosen4, Santosh Puszt1, Nikil Waite1, David Spellmeyer6, Alessandra Cesano7, Rachael Hawtin2, Anthony Shackl1, UCSB Pharma, Slough, United Kingdom, 2Nodality Inc., South San Francisco, CA.

**Background/Purpose:** Epratuzumab is a humanized monoclonal antibody targeting the B cell-specific protein CD22 and is in Phase 3 clinical trials in patients with systemic lupus erythematosus (SLE). Epratuzumab does not deplete B cells, rather, the mechanism of action centers on CD22 regulatory activity of B cell receptor (BCR) modulation, via inhibition of specific BCR-driven phosphorylation events (Syk, PLCγ2) and Ca2+ flux. The aim of this study was to assess the effects of epratuzumab on receptor activation and BCR signaling across multiple B cell subsets in peripheral blood mononuclear cells (PBMC) from a large cohort of lupus patients.

**Methods:** Single Cell Network Profiling (SCNP) is a multiparametric, flow-cytometry-based technology that enables simultaneous analysis of signaling networks in multiple immune cell subsets.2 BCR modulated signaling (anti-IgG/anti-IgM) was profiled by SCNP in PBMC from 60 healthy donors (HD) across naive (CD27-/IgD-) and switched memory (CD27+IgD+) B cell subsets. Surface receptor (CD22, CD19, proximal (Syk, PLCγ2)) and distal (Akt, Erk, S6, p38, IkBa, NFκB/p105) signaling was interrogated 5 or 15 minutes post modulation in the presence and absence of epratuzumab (10mg/ml), which had been pre-incubated with cells for 1 hour.

**Results:** Epratuzumab (10mg/ml), which had been pre-incubated with cells for 1 hour.

**Conclusion:** Epratuzumab activity in B cells was identified as induction of pCD22 Tyr152, most pronounced in naive B cells (p<0.0001). Broad inhibition of all examined BCR-proximal signaling (p<0.0001) was observed in the whole B cell population with the most pronounced effects observed in the switched memory B cell population. Strong inhibition of BCR modulated pCD19 (p<0.0001) was also seen in this population, which may contribute to inhibition of BCR activation events. Inhibition of distal signals was demonstrated specifically in the switched memory B cell population whilst conversely, in the naive B cell subset, evidence for activation of distal signaling (p<0.0001) was observed. Interestingly, weak activation of pAkt was observed in both naive and switched memory B cells.

**B-Cell Autoepitope and Tetramer Analysis Reveals Expansion of Apoptotic Autoantigens La and snRNP Reactive B Cells in BXD2 Mice.** Jennifer Hamilton5, Jun Li1, Qi Wu1, PingYi Yang1, Bao Luo1, Hao Li1, Troy Randall1, John Edwin Bradley1, Justin J. Taylor2, John D. Mountz3 and Hui-Chen Hu1. University of Alabama at Birmingham, Birmingham, AL, 2Fred Hutchinson Cancer Research Center, Seattle, WA, 3Birmingham VA Medical Center, Birmingham, AL.

**Background/Purpose:** Systemic lupus erythematosus (SLE) is characterized by production of highly pathogenic IgG autoantibodies (autoAbs). While serum autoAb profiling is standard, it remains challenging to isolate authentic autoreactive B cells that give rise to these autoAbs. Similar autoAbs are spontaneously produced in lupus-prone BXD2 mice that display apoptotic cell features and heightened type II signaling. The purpose of this study is to develop a comprehensive autoepitope and tetramer strategy to identify the dominantautoantgens (autoAg) and the underlying mechanisms promoting the development of autoreactive B cells in BXD2 mice.

**Methods:** A Peer2Peer Autoimmunity Microarray covering 3,653 database derived, linear B-cell autoepitopes was probed with 66 and BXD2 serum to determine IgM and IgG binding reactivity. Top peptides were selected for 3D crystal structural analysis. A panel of over 50 peptide epitopes were verified by ELISA and ELISPOT. Two epitopes from RNA-binding lupus La and 70 kDa U1snRNP were used to generate B cell tetramers for characterization of Ag-specific subpopulations of B cells.

**Results:** Stimulation mimicking T cell help broke anergy and forced BND cells to fully respond to antigenic stimulation by restoring normal signaling through the BCR. This was dependent on de novo protein synthesis as opposed to direct crossstalk between the BCR, IL-4 and CD40 signaling pathways. We traced the restoration of BCR signaling from downstream signaling stages such as intracellular calcium release to phosphorylation of Syk and Lyn kinase, which is located proximal to the BCR. We observed an inability of activation of Lyn in BND cells upon BCR-stimulation, while subsequent to IL-4/CD40L treatment, the activation state of Lyn was restored. Lyn kinase activity is principally regulated by CD45 phosphatase (activating) and Csk kinase (inactivating). By inhibition studies, we identified CD45 upregulation of CD45 surface expression on B cells stimulated with T cell and Csk kinase (inactivating). By inhibition studies, we identified CD45 inactivity of activation of Lyn in BND cells upon BCR-stimulation, while signaling stages such as intracellular calcium release to phosphorylation of pathways. We traced the restoration of BCR signaling from downstream signaling stages such as intracellular calcium release to phosphorylation of Syk and Lyn kinase, which is located proximal to the BCR. We observed an inability of activation of Lyn in BND cells upon BCR-stimulation, while subsequent to IL-4/CD40L treatment, the activation state of Lyn was restored. Lyn kinase activity is principally regulated by CD45 phosphatase (activating) and Csk kinase (inactivating). By inhibition studies, we identified CD45

**Conclusion:** The bona fide presence of RBP cryptic autoAbs that were not predicted by Ag prediction programs is consistent with the finding that defective clearance of apoptotic blebs in BXD2 mice leads to production of autoAbs that break B cell tolerance. signaling were identified in the naïve and memory populations. In switched memory B cells inhibition of pCD19 and downstream signals was demonstrated. In contrast, in naïve B cells activation of distal signals was observed. These data have implications for understanding the functional consequences of epratuzumab treatment on B cell pathologic activity in patients with autoimmune diseases such as SLE.

Pro-Inflammatory FcRL4+ Memory B Cells in Joints of RA Patients: Immunoglobulin Gene Characteristics and Antigen Specificity. Khaled Amara1, Lorraine Yeo2, Natalie Sipli3, Philip Titcombe3, Andrew Filer3, Karim Raza4, Dagmar Scheel-Toellner5 and Vivianne Malstrom6. 1Rheumatology Unit, Department of Medicine, Karolinska University Hospital, Karolinska Institutet, SE-17176 Solna, Stockholm, Sweden, 2Translational Research Group, Centre for Translational Inflammation Research, College of Medical and Dental Sciences, University of Birmingham, Birmingham B15 2TT, UK, Birmingham, United Kingdom, 3Rheumatology Research Group, MRC Centre for Immune Regulation, School of Immunity and Infection, University of Birmingham, Birmingham, United Kingdom, 4Rheumatology Unit, Karolinska University Hospital, Solna, Karolinska Institutet, Stockholm, Sweden.

Background/Purpose: Our recent findings identified a subset of pro-inflammatory memory B cells in the RA synovium characterized by the expression of the surface protein Fc receptor like 4 (FcRL4)1. FcRL4+ B cells produce RANKL, and express high levels of TNF mRNA, indicating a destructive, pro-inflammatory role for this B cell subpopulation. It is however unclear how synovial FcRL4+ve B cells develop, whether they have undergone hypermutation in germinal centers and the nature of their relationship with FcRL4-ve B cells at the same site. The aim of this project was to investigate whether autoreactive features would accumulate in the FcRL4+ve B cell subset by investigating the antigen-specificity and Ig gene characteristics of FcRL4+ve and FcRL4-ve B cells from both synovial tissue and blood of RA patients.

Methods: Single FcRL4+ve and -ve memory B cells were sorted from synovial tissue (n=2) and synovial fluid (n=5) of patients with active RA. Their Ig variable region genes were sequenced and subsequently expressed to generate recombinant monomeric antibodies. Antigen-specificities of the generated monoclonal antibodies were determined by ELISA.

Results: In total, we have cloned and sequenced B cell receptors from 332 individual B-cells (121 from FcRL4+ and 160 from FcRL4- cells). The Ig gene sequence analyses demonstrated that the Ig repertoire was highly diverse with no major differences in the IGH and IGL or IGL gene segment usage or IGH CDR3 features between FcRL4+ve and FcRL4-ve memory B cells. From the sequenced clones we have so far generated 38 recombinant monoclonal antibodies (from both FcRL4+ve and FcRL4-ve B cells) and determined their specificity for citrullinated candidate autoantigens. We found no difference in the frequency of autoreactive Ig in the FcRL4+ve versus -ve cells. 13 antibodies reacted to citrullinated antigens (including α-actinase, fibrinogen, and vimentin) without recognizing the unmodified arginine control peptides.

Conclusion: We conclude that the FcRL4+ve and FcRL4-ve memory B cells, while functionally and phenotypically distinct, are both post-germinal center hypermutated B cell subsets with similar Ig gene features. We have not identified a relationship between FcRL4 expression and overall B cell receptor characteristics and antigen specificities suggest that the two B cell subpopulations may originate from similar immune responses differentiating into functionally distinct subsets.

**Results:** Wildtype mice treated with IL-10 receptor blockade succumbed to MAS-like hyperinflammation manifest as weight loss, splenomegaly, bicytopenias, and hypercortiokinemena during LCMV infection. IFN-γ+ and IFN-α+ mice were not protected from LCMV-induced disease in this model, as they developed severe weight loss, splenomegaly, cytopenias, hypercortiokinemena, and more severe mortality when IL-10 receptor was blocked.

**Conclusion:** IL-10 receptor blockade leads to heightened immunopathology in the setting of LCMV infection similar to MAS-like hyperinflammatory disease. Unlike other hyperinflammatory syndromes, this immunopathology is independent of IFN-γ and IFN-α, and highlights the capacity of other inflammatory mediators to cause viral-induced hyperinflammation during IL-10 receptor blockade. Furthermore, these data highlight a novel mechanism that could contribute to MAS-like disease whereby defects in IL-10 production and/or sensing could exacerbate hyperinflammatory immunopathology induced by viral infection without genetic defects in cellular cytotoxicity.

**Novel Function of Tocilizumab As a Modulator of Interleukin-27-Mediated Anti-Inflammatory Responses.** Misato Hashizume1, Jun Kikuchi2, Keiko Yoshimoto2 and Tsutomu Takeuchi. Chugai Pharmaceutical Co., Ltd., Gotemba, Japan, 1Ko University School of Medicine, Tokyo, Japan.

**Background/Purpose:** The immunological roles of interleukin 27 (IL-27) have been reported in the function of regulatory T cells (Treg), monocytes and osteoclasts, and these cells are involved in various autoimmune diseases, such as rheumatoid arthritis (RA), lupus, systemic sclerosis, and psoriasis. There is increasing information about how the function of IL-27 regulates in autoimmune disease. IL-27 is a heterodimeric cytokine composed of IL-27p28 and EB13, which are analogous to IL-6 and soluble IL-6 receptor (sIL-6R) respectively. In this study, we investigated whether a possible role of sIL-6R in regulating IL-27 function.

**Methods:** CD4+ cells were isolated from peripheral blood in RA patients. MCP-1 was measured by ELISA in the culture supernatant of incubated with TNF-α, IL-27, sIL-6R, anti-IL-6 antibody and anti-IL-6R antibody (tocilizumab). In the experiments of osteoclasts, CD4+ cells were cultured with RANKL and M-CSF in the presence of IL-27, sIL-6R, anti-IL-6 antibody and tocilizumab for 4 days and the number of osteoclasts was counted. Consecutive RA patients who received 8mg/kg of tocilizumab every 28 days were not protected from LCMV-induced disease in this model. Over the treatment with tocilizumab, the proportions of Treg and monocytes in RA patients. These data suggest that tocilizumab may be involved in modulating the anti-inflammatory responses of IL-27.

**Conclusion:** Tocilizumab may be involved in modulating the anti-inflammatory responses of circulating Treg and monocytes in RA patients. These data suggest that tocilizumab may be involved in modulating the anti-inflammatory responses of IL-27.

**G Protein Signaling Modulator 3 (GPSM3) Deficiency Is Protective In Inflammatory Arthritis Models and Altered GPSM3 Gene Products Correlate With Single Nucleotide Polymorphisms in Humans.** Teresa K. Tarrant1, D. Stephen Serafin2, Elizabeth Sugg3, Roman Timoshchenko4, Rachel M. Billard2, David P. Siderovski5 and Kristy Richards1. 1Arthritis Research Center, University of North Carolina at Chapel Hill, Chapel Hill, NC, 2West Virginia University School of Medicine, Morgantown, WV, 3Dept. of Genetics, University of North Carolina at Chapel Hill, Chapel Hill, NC.

**Background/Purpose:** GPSM3, a newly described regulator of heterotrimeric G protein signaling, is selectively expressed in hemopoietic cells with high expression in monocytes. We have shown that Gpms3 deficient (-/−) mice are protected from Collagen Antibody Induced Arthritis due in part to their attenuated monocyte responses, including decreased ex vivo migration to the chemokinines CX3CL1, CCL2, and chemerin, and enhanced apoptosis, which leads to an observed decrease in proinflammatory intra-articular IL-6 and IL-1β transcripts in the joint. Given the restricted expression of GPSM3 in leukocytes and the functional phenotypes observed in immune cells lacking GPSM3 expression, we chose to examine effects of GPSM3 deficiency in Collagen Induced Arthritis (CIA) and to analyze whether single nucleotide polymorphisms (SNPs) within the human GPSM3 gene locus, associated with a decreased incidence of autoimmunity, correlate with altered GPSM3 gene products.

**Methods:** Gpms3−/− and Gpms3+/+ DBA1 mice were immunized with heterologous type II collagen in Freund’s Adjuvant with a booster immunization at day 21 per published protocols. Arthritis was assessed by a blinded observer for paw swelling and clinical disease score (0–4). Paws were processed at day 42 for histopathology. Serum B-cell activating factor (BAFF) was measured by commercial ELISA (R&D Systems) per manufacturer’s instructions on day 14. DNA and RNA was isolated from healthy human subject blood using Qiagen purification reagents. Genotyping for SNP (A (minor)/G (major) transition substitution) was performed using commercially available TaqMan SNP Genotyping Assay (SNP ID rs204989) from Applied Biosystems by Life Technologies. qRT-PCR primers for known GPSM3 transcripts −001, −002, −003, and −004 were designed from NCBI (−001 and −002) and Ensembl (−003 and −004) databases, and validated by gel electrophoresis for sequence length, sequencing, melt curve analysis, and PrimerBlast. qRT-PCR of cDNA from healthy human subject blood was performed using a Bio-Rad CFX96 Real-Time System and standard protocols. Data was calculated as relative expression compared to the housekeeping gene GAPDH.

**Results:** Gpms3−/− mice are protected from CIA and have significantly decreased serum BAFF levels. Healthy human subjects carrying protective SNPs that correlate with decreased RA and other autoimmune diseases have decreased levels of transcripts GPSM3-001, −002, and −004, but significantly increased levels of the transcript GPSM3-003, which is thought to be subjected to nonsense-mediated decay.

**Conclusion:** Our goal from these studies is to determine whether GPSM3 has immune system-modulating potential for the treatment of autoimmune diseases with particular focus on inflammatory arthritis. Gpms3−/− mice are protected from two models of inflammatory arthritis through mechanisms involving monocyte function. GPSM3 has altered mRNA transcripts in healthy human subjects with SNPs that correlate with decreased RA and other autoimmune diseases, suggesting differential gene regulation.

**Epigallocatechin-3-Gallate (EGCG) Suppresses IL-1β-Induced IL-6 and IL-8 Synthesis By Selectively Inhibiting TAK1 Activation in Human Rheumatoid Arthritis Synovial Fibroblasts.** Anil Singh1, Sharayah Riegsecker2, Sadiq Umar1 and Salahuddin Ahmed1. 1Washington State University, Spokane, WA, 2University of Toledo, Toledo, OH.
**Background/Purpose:** In rheumatoid arthritis (RA), the role of interleukin-1β (IL-1β) signaling proteins (IRAK-1/TAK-1/TRAF-6) proximal to IL-1 receptor in mediating proinflammatory response is not completely understood. Using IL-1β-induced IL-6 and IL-8 production in RA synovial fibroblasts (RA-FLS), we examined the role of key signaling molecules critical in mediating its inflammatory response. We also tested if EGCG, a potent anti-inflammatory compound, inhibits IL-1β signaling protein to suppress IL-6 synthesis in RA-FLS.

**Methods:** RA-FLS were treated with IL-1β for different time alone or in the presence of EGCG. Western blotting analysis was utilized to study activation/phosphorylation of different IL-1β signaling proteins. In vitro kinase activity of IRAK-1 was determined using ADAPTA kinase assay. Changes in the ubiquitination patterns of IL-1β-induced RA-FLS was studied using immunoprecipitation (IP) assay. Using chemical inhibitors or siRNA for IRAK-1, TAK-1 or TRAF-6, their respective roles were examined studied using immunoprecipitation (IP) assay. Using chemical inhibitors or siRNA method also showed a marked inhibition of IL-6 production by TAK-1 or IRAK-1 siRNA. Although EGCG inhibited IL-1β-induced IRAK-1 kinase activity by almost 65%, it did not prevent the IL-1β-induced proteosomal degradation of IRAK-1 in RA-FLS. To our surprise, EGCG selectively inhibited IL-1β-induced TAK-1 phosphorylation in a dose-dependent manner (p<0.05; n=4). Interestingly, we observed that the levels of TRAF-6 remained unchanged upon IL-1β stimulation. IP of RA-FLS cell lysates with global Fk2 ubiquitin antibody and further Western blotting analysis showed that IL-1β activated TRAF-6 ubiquitination was not modulated by EGCG, suggesting TAK-1 as a potential therapeutic target in IL-1β signaling.

**Conclusion:** Our study provides a novel evidence of an important mediatory role of TAK-1 in IL-1β signaling in RA-FLS and warrants further testing of EGCG or its synthetic analogs as TAK-1 inhibitors for the treatment of RA.

**Elevated Levels of Soluble Inflammatory Mediators and Lupus-Specific Connective Tissue Disease Questionnaire Scores Discern Unaffected First Degree Relatives of Lupus Patients from Unaffected Individuals**

The current state of lupus is primarily based on affected relatives. Characterization of unaffected relatives is essential to determine the course of the disease.

**Methods:** A unique resource of SLE patient family members was developed with the Department of Veterans Affairs. Using a unique resource of SLE patient family members, the approach to developing SLE is essential to curtail inflammatory damage and select individuals for prevention trials. First-degree relatives (FDRs) of lupus patients have an increased risk of developing SLE. Using a unique resource of SLE patient family members with longitudinal samples available, the goal of this study is to determine factors that distinguish FDRs who remain unaffected from over time.

**Background/Purpose:** Identifying populations at risk of SLE is essential to curtail inflammatory damage and select individuals for prevention trials. First-degree relatives (FDRs) of lupus patients have an increased risk of developing SLE. Using a unique resource of SLE patient family members with longitudinal samples available, the goal of this study is to determine factors that distinguish FDRs who remain unaffected from over time.

**Methods:** We evaluated plasma samples from 154 unaffected FDRs of known SLE patients with samples available from previous genetic studies and who remained unaffected at follow-up evaluation (mean time to follow-up 6.8 years). FDRs were matched 2:1 by gender, race and age (±5 years) to 77 unaffected individuals unrelated to SLE patient (Controls). FDRs and Controls provided clinical and demographic information, and completed the SLE-specific portion of the Connective Tissue Disease Screening Questionnaire (CSQ) at baseline (BL) and follow-up (FU). BL and FU plasma samples were assessed for autoantibody production (ANA, anti-dsDNA, aCL, Ro, La, Sm, nRNP, and ribosomal P antibodies) and for 52 soluble inflammatory mediators (BLyS, APRIL, cytokines, chemokines, and shed TNF receptors). Logistic regression modeling of CSQ scores, number of autoantibody specificities, and select soluble mediators (via Random Forest) was utilized to evaluate whether certain factors distinguished unaffected FDRs from Controls.

**Results:** FDRs had significantly higher BL and FU CSQ scores than Controls (p<0.0001). CSQ scores were higher in female FDRs vs. male FDRs or female Controls (p<0.001). No significant difference in the number of positive autoantibody specificities were noted between FDRs and Controls. FDRs had significant (p<0.01) alterations in 38 of (52) soluble mediators compared to Controls, including innate and adaptive mediators of inflammation, chemokines, and TNF superfamily members. APRIL and BLyS, IFN-associated chemokines IP-10, MIG and MIP-1α, as well as the regulatory mediators IL-10 and TGF-β, were significantly higher in FDRs at BL and FU (p=0.002). A number of mediators (14 at BL and 18 at FU) found to best separate FDRs from Controls by Random Forest strongly correlated with CSQ scores (p=0.0002). Of these, levels of MIP-1α (p=0.008), MIG (p=0.019), GROα (p=0.001), ICAM-1 (p=0.007), and VEGF (p=0.004), along with CSQ scores (p=0.010), best distinguished FDRs from Controls in logistic regression models.

**Conclusion:** Unaffected FDRs of SLE patients demonstrate significantly altered levels of soluble inflammatory, as well as regulatory, mediators compared to matched, unrelated, unaffected Controls. These alterations are present despite lack of progression to classified SLE, suggesting that multiple perturbations in immune-mediated inflammatory processes present in family members of SLE patients may be offset by inhibitory factors, providing unique insights for potential autoimmune disease prevention or SLE disease treatment.

Michael J. Battistone, Andrea M. Barker, Marissa Groitzke, Peter Beck, Jeffery Berdan, Caroline M. line., JoAnn Rolando and Grant W. Cannon. Salt Lake City VA and University of Utah, Salt Lake City, UT.

**Background/Purpose:** While musculoskeletal (MSK) problems are common in primary care, the current formal education in the evaluation and management of these conditions is inadequate. Through funding from the Veterans Affairs (VA) Office of Academic Affiliations, we developed an interprofessional, interdisciplinary, mixed-method program to enhance the clinical education of medical students, residents, fellows, and trainees of other health professions.

**Methods:** The week-long course begins with didactics, is reinforced through technology-enhanced simulation and peer-teaching in small-group settings, and culminates in supervised ambulatory clinical experiences and reflective practice.

Participants learn to perform, describe, and document a systematic physical exam of the shoulder and knee, interpret these findings, and develop patient-centered management options in a framework of high value care. Faculty represent Internal Medicine (IM) (Primary Care, Rheumatology, Endocrinology), Orthopedics, and Physical Medicine and Rehabilitation (PM&R) disciplines. Course assessments include written surveys, 2-station Objective Structured Clinical Examination, and individual exit interviews. Results: Student and trainee participants in the 2013–14 academic year are summarized below. Survey response rate was 89%. Post-course competency in examining the shoulder and knee, and in reporting, interpreting, and managing the case using a framework of high-value care, was confirmed with 2-station OSCE.

Using Decision-Based Learning to Highlight Rheumatic Disease for Third-Year Medical Students. Karen Law1, J. Richard Pittman2 and Chad Miller2. 1Emory University School of Medicine, Atlanta, GA, 2Tulane University Health Sciences Center School of Medicine, New Orleans, LA.

Background/Purpose: Opportunities for exposure to rheumatology are limited in medical school, especially during the clinical years. In addition, because the rheumatic diseases represent a small portion of the National Board of Medical Examiners Subject Examination (SHELF exam) for the Internal Medicine clerkship, clerkship directors are reluctant to devote limited class time to rheumatology. This project aims to improve medical student exposure to rheumatology during the third-year Internal Medicine Clerkship via Decision-Based Learning (DBL), a simulated case-based teaching technique. Learners work in teams on a challenging clinical case. Teams are given a description of the patient's history and physical examination; each team collaborates to generate a differential diagnosis, then order tests and studies to work up the case. A simulated "bank" of tests and studies is available, with each test coming with a "price" that the team is charged. The teams compete to solve the case by ordering and interpreting studies while also spending the least amount of money. Because of the cost-conscious and competitive nature of the exercise, learners are incentivized to employ prudent hypothesis testing and diagnostic reasoning to decide what is "the next best step" to arrive at the diagnosis.

DBL facilitates rheumatology exposure within the broad context of internal medicine, a format more appropriate for the medical student level than typical disease-specific rheumatology curricula. In addition, the DBL format highlights the diagnostic complexity of rheumatic cases. Students also practice critical thinking and cost consciousness, areas of medical education that are frequently lacking.

Methods: The project introduced DBL to third-year medical students during their clerkship in Internal Medicine. Control sessions consisted of usual lecture-style didactics. Learners were given a survey after each session to rate their learning experience.

Results: Student feedback for DBL sessions was significantly higher than for control didactic sessions (p < 0.01). 67% of learners rated DBL a "10" on a 10-point Likert scale compared to 35% for control (p < 0.01). Positive responses to DBL were also noted in the survey comments:

- "Really productive exercise; thought provoking"
- "Very high-yield, learned lots of new things"
- "Made us think about what to order & why-I don't feel we have gotten much experience with that during the rotation"

Conclusion: A novel case-based teaching technique facilitated medical student exposure to rheumatology during their clerkship in Internal Medicine. DBL resulted in significantly higher ratings of didactic sessions compared to traditional lecture-style didactics. Learners found the DBL sessions to be engaging and educationally valuable. This interactive teaching method can enhance the learning experience during the Internal Medicine clerkship; the realistic context in which Rheumatology topics are addressed may make it more appealing for Clerkship Directors to adopt. These findings support future evaluation of DBL with a case-control study to determine efficacy in the principal areas of Rheumatology-specific knowledge, diagnostic reasoning, and cost awareness.

Rheumatology-Specific Milestones for a Musculoskeletal Radiology Curriculum. Michelle Newkirk1, Liem Mansfield1, Jay H. Higgins2 and Daniel Battafarano3. 1San Antonio Military Medical Center, JBSA - Ft Sam Houston, TX, 2San Antonio Military Medical Center, JBSA - Fort Sam Houston, TX.

Background/Purpose: In 2012, the Accreditation Council for Graduate Medical Education (ACGME) announced the required implementation of standardized milestones with entrustable professional activities (EPAs) for the semi-annual evaluation of resident/fellow performance which must be implemented by November 2014. However, little guidance was rendered as to the incorporation of these milestones and EPAs into the curriculum of a subspecialty training program. Our rheumatology fellowship has had a formal musculoskeletal (MSK) radiology rotation for the past five years as part of its core curriculum and has integrated internal medicine subspecialty curriculum milestones with MSK radiology specific EPAs into this curriculum.

Methods: Utilizing a modified Delphi technique via e-mail, faculty and current fellows from the program established a consensus on EPAs for MSK radiology. The EPAs were individually rated using a nine-point Likert scale, with 1 being disagreement with the EPA and 9 being the most agreement. Agreed upon EPAs were then used as a foundation for the development of curricular milestones with MSK radiology specific EPAs into this curriculum.

Results: Etate faculty members and 2 rheumatology fellows participated in the process. Six EPA's were initially developed, and after two rounds of comments with wording and scoring, all six EPAs rated in the highest agreement scores (see table). Curricular milestones for MSK radiology were then established in keeping with these EPAs. These curricular milestones were integrated into our core MSK radiology lecture series.

Table 1: Entrustable Professional Activities (EPAs)

<table>

<tr>
<td>3. Interpret signs of acute and chronic musculoskeletal disease on radiography and know when to consult a radiologist for further evaluation and interpretation</td>
</tr>
</tbody>
</table>

S1259
Conclusion: The interpretation and application of MSK radiology is critical in the training of a rheumatology fellow. Incorporating a dedicated radiology rotation which addresses specific milestones and EPAs is one way of ensuring trainees are exposed to a quality, uniform curriculum that meets the ACGME’s next accreditation system requirements.

Training the Rheumatologists of Tomorrow: The Canadian Experience.

Alfred Cividino1, Volodko Bakowsky2, Susan Barr3, Louis Bessette4, Nader Khalidi5, Christian A. Pineau6, Janet E. Pope7, David Robinson8, Ken Shojania9, Elaine Yacyshyn10, Lynne Lohfeld11 and Diane Crawshaw12.

M.C.M aster University, Hamilton, ON, 1Dalhousie University, Halifax, NS, 2Heritage Medical Research Bldg, Calgary, AB, 3laval University, Quebec, QC, 4Division of Rheumatology, M.C.M aster University, Hamilton, ON, 5McGill University Health Center, Montreal, QC, 6St Joseph Health Care, London, ON, 7University of Manitoba, Winnipeg, MB, 8University of British Columbia, Vancouver, BC, 9University of Alberta, Edmonton, AB.

Background/Purpose: Many countries face a shortage of rheumatologists. Based on an accepted benchmark of 1 specialist per 50,000 people as the number needed for effective patient care, recent figures show severe shortages in the U.S. and Canada. This qualitative environmental scan was designed to identify what faculty, administrators and learners associated with Canadian postgraduate rheumatology programs identify as appropriate means and messages that programs could use to attract future trainees.

Methods: Individual-level data from program faculty (F), administrators and learners (L) across Canada (n = 103) were collected via an online survey (n = 25). Data were subjected to Thematic Framework Analysis to identify commonalities across sites to determine ways to address the rheumatology manpower shortage. Quotes are provided as examples.

Results: Participants: There were 103 respondents from nine programs including learners (medical students, junior residents (PGY 1–3) rheumatology residents (PGY 4–6) or new graduates); program and division directors and their assistants; and faculty in academic centres or community practices.

Two-thirds of the survey respondents were female.

Ways to Increase Interest in Rheumatology: The need for rheumatologists was widely recognized. Respondents advocated targeting both under-graduates ("People who influenced me were [role models] I had as a medical student" [F]) and junior residents in Internal Medicine. Proposed methods included increasing exposure to rheumatology in undergraduate programs through formal lectures and courses, clinical skills and other hands-on training sessions, faculty available to shadow or mentor learners and postgraduate weekend information and training sessions, mandatory rotation for Internal Medicine residents' internships and career counseling.

Messaging to Promote Rheumatology: Messages to brand rheumatology as an attractive specialty included the intellectual challenge ("This field fascinates me" [L]; "novel immunotherapies make it very exciting" [F]), stimulating workday ("nice mix of procedural and cerebral work" [L]), positive relationships with colleagues and patients ("According to a recent survey we are the happiest specialists" [F]), alleviating suffering ("We know how to treat arthritis now" [L]), good quality of life and excellent job prospects ("the health care system needs you" [F]).

Conclusion: We found consensus on the need to inform potential trainees about rheumatology early in their education through a variety of messages and methods. Because of the shortage of rheumatologists it is important to increase awareness and information about the field by selectively using limited resources. The next step would be to collaboratively develop, test and evaluate tools designed to help increase the number of future rheumatologists, which will be applicable in many locales.

Clinical Training Opportunities in Two Innovative Ambulatory Resources: The Primary Care Musculoskeletal Clinic and Center of Excellence Multidisciplinary Clinic.

Michael J. Batstone, Andrea M. Barker, Marissa Grotzke, Peter Beck, Jeffrey Berman, Phillip Lawrence and Grant W. Cannon. Salt Lake City VA and University of Utah, Salt Lake City, UT.

Background/Purpose: While musculoskeletal (MSK) problems are common in primary care, current training models do not adequately prepare primary care providers (PCPs) to deal with these issues. With funding from the Veterans Affairs (VA) Office of Academic Affiliations (OAA), we developed a Center of Excellence (COE) for MSK Care and Education to meet this training need for health care professional trainees.

Methods: Two new weekly outpatient clinics, the Primary Care MSK (PC-MSK) and the Multidisciplinary (COE-MSK) Clinics were developed as key components of the COE. The PC-MSK is staffed by a rheumatologist and a physician assistant (PA) with orthopaedic experience. The COE-MSK is staffed by a rheumatologist, a rheumatologist, orthopaedic surgeon, physia-trist, and a PCP. All categorical internal medicine (IM) interns, orthopaedic interns, PM&R residents, and rheumatology fellows participate in this clinic over the course of the academic year. Additional IM residents, medical students, nurse practitioner students and physician assistant students are also included as space allows.

Results: In 2013–14, 80 trainees participated in the PC-MSK and COE-MSK clinics. The distribution of disciplines and professions represented in this multi-level cohort are shown in Table 1.

Since June 2013, 330 patients have been seen in these clinics. As shown in Table 2, most are referred from primary care, mainly by providers in non-resident clinics. Most non-resident referrals were to the PC-MSK clinic, all others tended to request the multidisciplinary COE-MSK clinic.

Conclusion: These clinics provide unique and innovative opportunities for a broad range of trainees in a rich interdisciplinary and interprofessional educational environment. Additionally, these clinics are a valuable resource to primary care providers, specialty physicians, and patients for prompt and comprehensive care for veterans with either limited or complex MSK problems.
Assessing Rheumatology Fellows’ Teaching Skills Using the Objective Structured Teaching Exercise (OSTE). 

Eli M. Miloslavsky1, Marc B. Bolster1, Kenneth S. O’Rourke1 and Lisa G. Criscione-Schreiber1, 2
1Massachusetts General Hospital, Boston, MA, 2Wake Forest School of Medicine, Winston-Salem, NC, 3Duke University Health System, Durham, NC.

Background/Purpose: The interaction between rheumatology fellows and internal medicine residents in the setting of a consult offers an important opportunity for resident learning. However, teaching in the setting of a consult interaction can be challenging due to time constraints and lack of a longitudinal relationship between the resident and fellow. Fellows’ teaching skills in the setting of the consult interaction have not been evaluated. We conducted a pilot study utilizing the Objective Structured Teaching Exercise (OSTE) to evaluate rheumatology fellows’ teaching skills.

Methods: First and second year rheumatology fellows from 5 training programs participated in a one-station OSTE during a 7 station rheumatology Objective Structured Clinical Examination (OSCE) in February 2014. Following the OSCE format, fellows were given 10 minutes to teach a standardized resident in the setting of a simulated consult and relay their consult recommendations, followed by 2 minutes of feedback. Prior to beginning the station fellows were given written instructions on the objectives of the exercise as well as a resident admission note describing the patient (32 year old male with monoarthritis). The OSTE was proctored by 3 faculty members (including author [EMM]) and utilized 3 standardized residents. Each fellow was evaluated by one faculty member and the standardized resident using an 8-point instrument adapted from a validated OSTE rating tool. Prior to the OSTE, faculty and standardized residents received written materials describing the station and the rating tool and underwent a 30-60 minute training.

Results: Nineteen rheumatology fellows participated in the OSTE (11 first years and 8 second years). Fellows’ overall teaching effectiveness had a mean score of 3.75 out of 5 (Table). Of seven specific skills evaluated, fellows were rated highest on their ability to present organized material and lowest on their ability to adjust for age and menopausal factors with subsequent development of serologic RA phenotypes in 2 prospective cohorts.

Method: Data were analyzed from Nurses’ Health Study (NHS, 1976–2010) and NHSII (1989–2011). In NHS 121,701 female nurses aged 30–55 and in NHSII 116,430 female nurses aged 25–42 were followed via biennial questionnaires on lifestyle factors and disease outcomes. In total, 1,089 incident RA cases were confirmed by questionnaire and chart review. Seropositive RA was defined as more/less or ACPA by chart review or lab measurement. We used Cox proportional hazards models to obtain HR (95% CI) of seropositive or seronegative RA associated with menopausal status, age at menopause, type of menopause, severity of hot flashes and ovarian years, adjusting for age, BMI, smoking, breast-feeding, and parity.

Results: Women aged 45 or more had an increased risk of seronegative RA in all age groups, compared with women aged 25–44, with peak HR at ages 55–59. Women aged 50 or more had an increased risk of seropositive RA, with peak HR at ages 55–59, but the risk attenuated after age 60. Post-menopausal women had an increased risk of seronegative RA after adjusting for age and other potential confounders (NHS: HR 1.8, 95% CI 1.1–3.0; NHSII: HR 2.5, 95% CI 1.5–4.2; pooled HR 2.1, 95% CI 1.5–3.1) without marked differences according to type of menopause. Early age at menopause associated with an increased risk of seronegative RA (NHS: HR 2.5, 95% CI 1.2–3.4; NHSII: HR 3.0, 95% CI 1.7–5.1; pooled HR 2.4, 95% CI 1.5–3.5), regardless of type of early menopause. Moderate/severe hot flashes was mainly associated with an elevated risk of seronegative RA (NHS HR =2.4, 95% CI 1.4–4.3; NHSII: 3.7, 95% CI 2.0–6.8; pooled HR 3.0, 95% CI 2.0–4.5). None of the menopausal factors were significantly associated with seropositive RA.

Conclusion: Age and menopausal factors have an increased risk of both RA phenotypes, but this risk attenuates after age 60 for seropositive RA. Post-menopausal factors are strongly associated with seronegative RA, but not seropositive RA, suggesting potential differences in disease etiology.

ACR Concurrent Abstract Session

Epidemiology and Public Health IV: Rheumatoid Arthritis Pathogenesis

Tuesday, November 18, 2014, 4:30 PM – 6:00 PM

2887

Post-Menopausal Factors and the Risk of Seropositive and Seronegative Rheumatoid Arthritis Phenotypes: Results from the Nurses’ Health Study, Camilla Bengtsson1, Susan M aspés2, Jeffery A. Sparks2, Karen H. Costenbader3 and Elizabeth W. Karlson1. 1Karolinska Institutet, Stockholm, Sweden, 2Brigham and Women’s Hospital, Harvard Medical School, Boston, MA.

Background/Purpose: A mong women, the peak incidence of rheumatoid arthritis (RA) is reported to be 45–74 years of age. In addition, it has been suggested that the post-menopausal transition, especially at younger ages (Pikwer, Ann Rheum Dis, 2012), is related to an increased risk of RA, but the literature is scarce. Whether menopause has different impact on seropositive/seronegative RA phenotypes remains to be elucidated. Our aim was to explore whether age and menopausal factors were independently associated with subsequent development of serologic RA phenotypes in 2 prospective cohorts.

Methods: Data were analyzed from Nurses’ Health Study (NHS, 1976–2010) and NHSII (1989–2011). In NHS 121,701 female nurses aged 30–55 and in NHSII 116,430 female nurses aged 25–42 were followed via biennial questionnaires on lifestyle factors and disease outcomes. In total, 1,089 incident RA cases were confirmed by questionnaire and chart review. Seropositive RA was defined as +RF or ACPA by chart review or lab measurement. We used Cox proportional hazards models to obtain HR (95% CI) of seropositive or seronegative RA associated with menopausal status, age at menopause, type of menopause, severity of hot flashes and ovarian years, adjusting for age, income, BMI, smoking, breast-feeding, and parity.

Results: Women aged 45 or more had an increased risk of seronegative RA in all age groups, compared with women aged 25–44, with peak HR at ages 55–59. Women aged 50 or more had an increased risk of seropositive RA, with peak HR at ages 55–59, but the risk attenuated after age 60. Post-menopausal women had an increased risk of seronegative RA after adjusting for age and other potential confounders (NHS: HR 1.8, 95% CI 1.1–3.0; NHSII: HR 2.5, 95% CI 1.5–4.2; pooled HR 2.1, 95% CI 1.5–3.1) without marked differences according to type of menopause. Early age at menopause associated with an increased risk of seronegative RA (NHS: HR 2.5, 95% CI 1.2–3.4; NHSII: HR 3.0, 95% CI 1.7–5.1; pooled HR 2.4, 95% CI 1.5–3.5), regardless of type of early menopause. Moderate/severe hot flashes was mainly associated with an elevated risk for seronegative RA (NHS HR =2.4, 95% CI 1.4–4.3; NHSII: 3.7, 95% CI 2.0–6.8; pooled HR 3.0, 95% CI 2.0–4.5). None of the menopausal factors were significantly associated with seropositive RA.

Conclusion: In these prospective cohorts, women of older ages have an increased risk of both RA phenotypes, but this risk attenuates after age 60 for seropositive RA. Post-menopausal factors are strongly associated with seronegative RA, but not seropositive RA, suggesting potential differences in disease etiology.
The Association Between Changes in Inflammation and High Density Lipoprotein Cholesterol Efflux Capacity in Rheumatoid Arthritis. K P Liao,1 Martin Playford,2 Michelle A. Frits,3 Christine K. Iannaccone,1 Jonathan S. Coblyn1, Michael E. Weinblatt1, Nancy A. Shadick1 and Nehal N. M. Nalwa.1,2,3 Brigham and Women’s Hospital, Boston, MA, 4National Heart, Lung, and Blood Institute, Bethesda, MD, 5Brigham and Women’s Hospital; Harvard University, Cambridge, MA, 6University of Pennsylvania, Philadelphia, PA.

Methods: We conducted this study in a single center longitudinal RA cohort from a large academic center with RA clinical data, CRP and blood samples collected annually. We randomly selected 100 patients who experienced a reduction in inflammation defined as >10mg/L CRP decrease between any two time points one year apart. The first time point was defined as the baseline. Subjects on statin therapy one year before and during the one year follow up were excluded. We measured HDL efflux capacity in serum samples at baseline and one year follow-up quantified using a validated ex vivo system involving the incubation of macrophages with apolioprotein B-depleted serum. We used the paired t-test to determine significant differences between baseline and follow-up HDL cholesterol efflux values. We assessed the correlation between the change in CRP levels (natural log (baseline CRP-1 year follow-up CRP)) with percentage (%) change in HDL cholesterol efflux capacity using a Spearman’s correlation.

Results: We studied 92 subjects who experienced a reduction in inflammation as measured by CRP between baseline and one year follow-up with adequate serum volume. The mean age was 57.7 (SD 12.3), 89.3% were female, 78.5% were ACPA positive. The mean baseline CRP was 48.4mg/L (SD 59.3), and HDL efflux capacity was 1.04 (SD 0.17). At one year follow-up, the mean reduction in CRP was 41.0mg/L (SD 54.6). We observed an increase in HDL cholesterol efflux capacity of 6.7% (p<0.0001). A reduction in CRP was significantly correlated with an increase in HDL cholesterol efflux capacity (r=0.24, p=0.02) (Figure).

Conclusion: Although HDL cholesterol efflux capacity is considered to be a stable measure of HDL function over time in the general population, in RA subjects we observed a concomitant improvement in HDL function by efflux capacity with reductions in inflammation. These findings highlight a potential mechanism linking inflammation and CV risk in RA.
Does a Family History of RA Influence the Clinical Presentation and Treatment Response in RA? Thomas Frisell1, Saeds Saervasdottir2 and Johan Askling3. 1Clinical Epidemiology Unit, Dept of Medicine, Karolinska Institutet, Stockholm, Sweden, 2Rheumatology Unit, Karolinska University Hospital, Stockholm, Sweden.

Background/Purpose: Since family history of RA is among the strongest risk factors for developing the disease, individuals suspected to have RA are routinely asked about their relatives’ disease history. Being a summary measure of a range of genetic and non-genetic risk factors, it would seem likely that family history of RA carries information not only on risk of onset of RA, but also on prognosis, and/or that it may be more strongly associated with certain features of this heterogenic criteria based syndrome. Despite the potential clinical value, and great interest from patients, the role of family history of RA as a clinical marker has been little studied, probably due to the difficulty in ascertaining valid information on familial RA and clinical outcomes.

Methods: We performed a cohort study using prospectively recorded data from Swedish nationwide registers. The cohort was defined as all early RA patients (symptom onset ~12 months before inclusion) with a diagnosis of seropositive or seronegative RA in the Swedish Rheumatology register, who started methotrexate monotherapy as first DMARD treatment 2000–2011, and who had parents registered in the Swedish multi-generation register. First degree relatives of cohort members were identified through the Swedish Multi-Generation Register, and the presence of RA among relatives was assessed through the National Patient Register.

The association of RA in one or more first degree relatives to baseline clinical characteristics and treatment response (according to the DAS28-based EULAR response criteria), treatment switch, and change in disease activity measures at 3 and 6 months was estimated using linear regression and generalized logistic regression models.

Results: In our cohort, 380 (9%) of 4210 patients had a first degree relative with RA by their time of RA diagnosis. RA patients with compared to without a family history of RA were more often seropositive (75%/69%), but there were no other significant differences in baseline clinical characteristics (e.g., mean HAQ 0.95/1.01, mean DAS28 5.04/5.06, mean disease duration 0.48/0.49 years). Neither were there any significant differences in treatment response or disease progression at 3 or 6 months, a lack of association that remained after adjustment for sex, age, birth year, and disease duration, and also when further adjusting for baseline DAS28, HAQ, and CRP (Table).

Conclusion: Using a large population-based cohort, we found that despite being a strong predictor of RA itself, family history of RA is not associated with a more severe presentation of RA, nor with short term response to methotrexate monotherapy. Future studies could consider whether family history may be a predictor of long term prognosis or response to treatment other than methotrexate, and what this negative finding implies for the possibility of RA risk genes to also influence disease severity and treatment response.

Inflammatory Genes Are Associated with Autoantibodies in Rheumatoid Arthritis-Free Individuals Who Are At-Risk for Future Disease. Ryan W. Gan1, Kendra A. Young1, M. Kristen Demoruelle2, Michael H. Weisman3, Jane H. Buckner4, P. K. Gregersen5, Ted R. Mikuls6, James R. O’Dell6, Sharon B. Masson7, Thomas Frisell8, N. J. Askling3, None. Antares, 5; None; C. K. Iannaccone, None.

Background/Purpose: Using a large population-based cohort, we found that despite the presence of rheumatoid arthritis(RA)-related autoantibodies is associated with systemic inflammation, and that decreased consumption of anti-inflammatory omega-3 fatty acids (n-3 FA) is associated with RA-related autoantibody positivity. We examined whether selected genes in inflammatory pathways in which n-3 FA play a role are associated with the presence of RA-related autoantibodies in individuals without RA but at risk for the disease.

Methods: Participants were enrolled in The Studies of the Etiology of RA (SERA), which is a multisite observational study following a cohort of first-degree relatives of RA probands and a cohort enriched with the HLA-DR4 genetic variant, both of which are RA-free at their baseline visit. Participant DNA was screened at the Benaroya Research Institute for specific shared epitope subtypes of HLA-DR4 and HLA-DR1. Participants were positive for the shared epitope if they were either DR4 or DR1 subtype positive. Serum was measured for the following autoantibodies: anti-cyclic citrullinated peptide version 2 (CCP2), CCP3.1 (in a subset), rheumatoid factor (RF) by nephelometry, and RF isotypes (RF-IgM, RF-IgG, RF-IgA). Participants were considered positive for RA-related autoantibodies if they tested positive for any of these autoantibodies at their baseline visit.
Participants were typed for single nucleotide polymorphisms (SNPs) in Cox-2, TNFA, NF-KB, IKBkB, PPARRA, and PPARG at the Broad Institute using the Sequenom platform. The association between RA-related autoantibody positivity and inflammatory genes was assessed using logistic regression, accounting for the correlation within family members, and adjusting for age at visit, sex, and race.

**Results:** Demographic characteristics were similar between autoantibody positive (n=306) and autoantibody negative (n=1,576) participants (Table 1). We observed a significant association between increasing number of minor alleles for Cox-2 and NF-KB and autoantibody positivity (Table 2).

**Conclusion:** Our results suggest that Cox-2 and NF-KB could be associated with an increased likelihood of developing RA-related autoantibodies. The association observed with Cox-2 is of interest due to the enzyme’s role in producing inflammatory lipid molecules, while the association observed with NF-KB is of interest given the potential roles that NF-KB has in the RA disease process, including cytokine production and stimulating B cell differentiation to immunoglobulin-producing B cells. These results need to be explored in further detail.

**Genome-Wide Association Study of Osteoarthritis Progression: Results from the Osteoarthritis Initiative.**

**Background/Purpose:** Most genome-wide association (GWA) studies have focused on OA prevalence, but few have focused on OA progression. GWA studies of OA progression may help reveal new biology and drug targets that can be used to develop treatments that slow disease progression in OA patients.

**Methods:** We used an agnostic GWA analysis of ~8 million 1000 genomes imputed single nucleotide polymorphisms (SNPs) to identify genetic variation associated with structural knee OA progression. Our analyses were conducted in Caucasian participants from the Osteoarthritis Initiative (OAI), a multi-center natural history study of individuals who have or are at high risk for developing radiographic knee OA. A total of 1,756 participants who returned for a follow-up exam and had evidence of radiographic OA (Kellgren-Lawrence (K.L) grade ≥ 2) in one or more knees at baseline were included in the analyses (54% female, mean age = 67 ± 9 years). We defined progression as worsening of K.L grade or progression to total joint replacement (TJR). As a secondary phenotype, we exclusively evaluated progression to TJR. Participants were followed annually for four years. A bout 27% had worsening of K.L grade and 6% had TJR at follow-up. For these analyses, we used logistic regression models adjusted for age, sex, study site, and population stratification and assumed additive genetic models.

**Results:** We identified two SNPs that reached genome wide significance (P < 5x10^-8). One SNP on chromosome 18, rs9964101 (OR = 1.6, 95% CI = 1.4-1.7, P = 3.2x10^-8), is associated with worsening of K.L grade and another SNP on chromosome 4, rs76964101 (OR = 1.08, 95% CI = 1.00-1.17, P = 4.4x10^-6), is associated with progression to TJR. Both SNPs are located within intergenic regions, where rs9964101 is closest to SLY and rs76964101 targets that can be used to develop treatments that slow disease progression in OA patients.
is closest to SRD5A3 and KDR. SYT4 encodes synaptotagamin 4, which is expressed in the brain and may play a role in calcium dependent vesicular trafficking and exocytosis. There is some evidence that this protein may be involved in body weight regulation through negative regulation of oxytocin release. SRD5A3 encodes steroid 5 alpha-reductase 3, which is involved in maintenance of the androgen receptor activation pathway. KDR encodes a kinase insert domain receptor, which is a receptor for vascular endothelial growth factors and promotes proliferation, survival, migration, and differentiation of endothelial cells. There was no evidence for association of either SNP with OA prevalence, suggesting that these SNPs may be uniquely associated with OA progression.

Conclusion: We have identified two genome-wide significant SNPs that may be associated with structural knee OA progression. These SNPs reveal that neuronal regulation of obesity, androgen signaling, and vascular endothelial growth factors may play an important role in OA progression. Further work is ongoing to replicate these associations and identify the causative signal.

Relationship of Dermal Advanced Glycation End Products and Hand Osteoarthritis with Habitual Running

Background/Purpose: Hand Osteoarthritis (HOA) is characterized by the progressive destruction of articular cartilage and bone changes and is strongly and positively associated with age but the mechanism by which aging contributes to this increased susceptibility is largely unknown. Recently, the hypothesis that accumulation of advanced glycation end products (AGEs) that are associated with oxidative stress and aging might explain some or most of this association has been suggested. We compared skin autofluorescence as a measure of dermal AGEs and its association with the prevalence of HOA, symptomatic HOA, and the number of finger joints with osteophytes and joint space narrowing (JSN) as a measure of severity.

Methods: We performed a cross-sectional analysis of a purposeful sample of the Osteoarthritis Initiative (OAI) from a single site who had dermal AGEs measured by skin autofluorescence using SCOUT DS machine (Vera light Inc., Albuquerque, New Mexico) at the 36 month visit. We used an excitation wavelength of 375nm and emission wavelengths of 435-660nm. This wavelength is correlated with cross-links of collagen, FAD, and NADH. A mathematical algorithm is applied to spectrum results to adjust for age, hemoglobin, skin pigmentation and light scattering. Hand x-rays from the dominant hand were read for definite osteophytes with JSN at 48 months. We classified a person as having radiographic HOA if their hand x-ray had two or more finger joints (DIP, PIP, MCP) affected on different fingers. Symptomatic HOA was defined as having radiographic HOA and presence of hand/finger pain, aching or stiffness for more than half the days in past 30 days. Simple T tests or Pearson correlation coefficients were used to evaluate the the mean number of finger joints involved by tertiles of dermal AGE levels. Then Analysis of Covariance was performed to adjust for age and gender. T-tests comparing levels of dermal AGEs between those with and without HOA and with and without symptomatic HOA were performed.

Results: In a sub-sample from the OAI (n=200) with equal proportions of participants with and without abdominal adiposity we had hand x-rays read. Of this sample, 171 had dermal AGEs measured and analyses performed. Mean levels of AGEs were greater both for those with radiographic HOA (n=114) [29.3(4.8) vs. 27.1(5.0), p = 0.005], and symptomatic HOA (n=35) [30.5(2.8) vs. 28.1(4.8), p=0.01] compared to those without HOA or symptomatic HOA. Furthermore level of AGEs correlated significantly with the number of joints affected per hand (r=0.25, p<0.001) and exhibited a dose-response relationship in categorical analysis (with 2.34, 2.70 and 3.59 joints involved by increasing tertiles of dermal AGE levels after adjustment for age and gender (p trend <0.001).

Conclusion: Non-enzymatic glycation of dermal tissues as a proxy for the accumulation of AGEs in articular cartilage is associated with HOA, symptomatic HOA and the severity of HOA as measured by the number of finger joints affected in this cross-sectional study. Replication of these findings in prospective cohort studies and understanding of metabolic pathways that may modify or mediate the relationship of AGEs with HOA are indicated.

Habitual Running Any Time in Life Is Not Detrimental and May Be Protective of Symptomatic Knee Osteoarthritis: Data from the Osteoarthritis Initiative

Background/Purpose: Controversy exists regarding whether habitual running is beneficial versus harmful to the knee. Chronic mechanical overloading could potentially physically damage structures within the knee. Alternatively, runners have a lower body mass index (BMI), protective of knee osteoarthritis (OA). Most existing studies evaluating running and knee osteoarthritis (OA) have focused on elite male athletes, not generalizable to most of the population. Therefore, we aimed to evaluate the relationship of habitual running with symptomatic knee OA in the Osteoarthritis Initiative (OAI), a cohort recruited from the community not based on elite running status.

Methods: This is a cross-sectional study of OAI participants with knee x-ray readings, symptom assessments, and completed surveys on lifetime physical activity. At the 96-month visit, a modified version of the Lifetime Physical Activity Questionnaire (LPAQ) asked participants to identify the top 3 most frequently performed physical activities (=20 times in life) from ages 12 – 18, 19 – 34, 35 – 49 and ≥50 years old. Those indicating running as an activity were defined as a runner in that time period. Running at any time in life included runners from all time periods. Posterior-anterior semi-flexed knee radiographs were obtained at OAI 48-month visit and scored for Kellgren-Lawrence (KL) grade (0-4). Radiographic OA (ROA) was defined as KL ≥ 2. Frequent knee pain within a person required at least one knee have frequent knee pain at the OAI 48-month visit. Symptomatic radiographic OA (SOA) required that at least one knee had both ROA and frequent knee pain. A person with any total knee replacement was classified as having SOA.

We performed logistic regression analyses where the predictor was running any time in life and running in the specific age ranges. The outcomes were ROA, frequent knee pain, and SOA; adjusted analyses included covariates age, sex and BMI.

Results: 2439 participants were included, 55% were female, mean age was 64.7 (9.0) years and BMI was 28.5 (4.9) kg/m². 28% ran at some time in their lives; of those, 49%, 31%, 15% and 5% identified running in 1, 2, 3, and 4 of the time periods respectively. From lowest to highest BMI tertile, 35%, 28%, 24% and 22% were runners at any time in life.

Yes (n = 221) 22.2% 0.73 (0.52 - 1.01) 0.85 (0.60 - 1.20)

For outcomes of frequent knee pain and ROA, the results were similar to that of SOA.

Conclusion: Our findings suggest an exposure to non-elite running at any time in life is not associated with a higher odds of prevalent ROA, knee, hip, pain, and SOA. Those with the lowest BMI were most likely to identify running as a habitual activity. These findings were observed in a cohort recruited from the community not based on elite running status making these findings potentially more applicable to a broader population. Non-elite running at any time in life does not appear detrimental, and may be protective of SOA.

A Multi-Center Double-Blind, Randomized Controlled Trial (db-RCT) to Evaluate the Effectiveness and Safety of Co-Aministered Traumeel® (Tr14) and Zeel® (Ze14) Intra-articular (IA) Injections Versus IA Placebo in Patients with Moderate-to-Severe Pain Associated with OA of the Knee. Carlos Lozada1, Eve del Río2, Donald Reitberg3, Robert Smith1, Charles Kahn1 and Roland W. Moskowitz1. University of Miami Miller School of Medicine, Miami, FL, Miami, FL, 2Rio Pharmaceutical Services, LLC, Bridgewater, NJ, 3Rio Pharmaceutical Services, LLC, Bridgewater, NJ.

Background/Purpose: Tr14 & Ze14 is a combination of dilute biological and mineral extracts administered IA for painful knee OA. In response to clinician impressions of positive outcomes, a db-RCT to assess efficacy and safety compared to IA saline was deployed in the US.

Methods: Pts with moderate-to-severe chronic knee OA were randomized to 3 weekly IA injections of either Tr14 & Ze14 or saline by clinical investigators experienced with use of the IA injection route. The primary efficacy variable was change in knee pain from Baseline to End-of-Study (Week 17) as measured by the WOMAC OA Pain Subscale (Section A, 1–5 100 mm VAS). Secondary measures included Total WOMAC and subscores for stiffness (B), and physician global function (C), change in pain following a 50 ft walk (100 mm VAS), patient and physician global assessments. Clinical relevance was assessed by comparing proportions of patients with reductions from baseline in WOMAC A scores greater than a validated benchmark: Minimal Clinically Important Difference (MCID). This was chosen as −32.6 mm (the most conservative value) based on a study of outpatients with knee or hip OA where WOMAC VAS MCIDs ranged from −7.9mm to −32.6mm (see reference 59 Taubak et al., Ann Rheum Dis. 2005; 64(1):29–33 in the description of the WOMAC index published by ACR). Safety was assessed by monitoring of vital signs, physical examinations of the target knee, adverse events and concomitant medications.

Results: 232 patients were randomized and treated (All Tr14 & Ze14, n=119, All Placebo, n=113; Intention-to-Treat (ITT) Tr14 & Ze14, n=117, Placebo, n=111). Treatment arms were well balanced across demographic and baseline characteristics. Tr14 & Ze14 did not discriminate for WOMAC A Pain as expected after only 1 of 3 injections on Day 8 (p=0.3715), but subsequently was significantly different (p<0.05) on Days 15, 43, 57, 71, 85 and 99 (primary endpoint day), and approached significance on Day 29 (p=0.0686). Logistic regressions showed the proportion of MCID responders was not significant on Day 8. As this was an expected finding, it served as a no-effect internal-model-validation. Tr14 & Ze14 was significantly different (p<0.05) on all subsequent days except Day 29 (approached significance, p=0.059, Figure 1). SO pain was similarly discriminating as was the Physician global assessment. Total WOMAC and subscores B&C were directionally consistent with WOMAC A. There were no related SAEs. AEs were generally mild and unrelated to treatment. Local knee-related AEs, labs assessments, ECGs and vital signs were unremarkable and similar between treatments.

Conclusion: Tr14 & Ze14 provided statistically significant and clinically relevant pain relief on days 15 to 99 in comparison to placebo. In this double-blind, randomized, controlled trial, a biological/mineral multi-extract combination was shown to be a safe and effective treatment for pain in moderate-to-severe knee OA.

Exercise Therapy and/or Manual Therapy for Hip or Knee Osteoarthritis: 2-Year Follow-up of a Randomized Controlled Trial. J. Haxby Abbott1, Cathy Chapelle1, Daniël Pinto2, Alexis Wright3 and Jean-Claude Theis4. University of Otago, Dunedin, New Zealand, 1Northwestern University, Chicago, IL, 2High Point University, High Point, NC.

Background/Purpose: Although both exercise therapy and manual therapy have evidence supporting their effectiveness in people with hip and knee osteoarthritis (OA), few clinical trials have reported their incremental effectiveness compared with usual medical care, or their long-term effects.

Methods: In this randomized controlled trial with 2-year follow-up, adults meeting the American College of Rheumatology criteria for hip or knee OA were randomly allocated to receive either a) exercise therapy; b) manual therapy; c) combined exercise therapy and manual therapy; or d) no trial intervention in addition to usual medical care. Groups a-c were provided 10 treatment sessions: 7 sessions within the first 9 weeks plus 3 booster sessions (2 at 4 months and 1 at 13 months). A summary blinded to group allocation reassessed participants at 2 years. The primary outcome measures were the Western Ontario and McMaster (WOMAC) osteoarthritis index (24 questions, 0–10 scale, total range 0–240) and physical performance tests (timed up-and-go, 40m fast-paced walk, 30 second sit-to-stand).

Results: 186 (90.3%) of 206 participants recruited were retained at 2 years follow-up. At baseline, mean age was 66 years (range 37 to 92) and mean WOMAC was 100.8 (SD 53.8). Missing data were replaced using multiple imputation. Intention-to-treat analysis of covariance (ANCOVA) showed improvements in WOMAC at 2 years were superior for all three intervention groups compared with the usual care group (2-sided p<0.05). Participants receiving exercise therapy in addition to usual care showed gains of 31.7 WOMAC points (95% CI 10.0, 53.3); effect size 0.57 (Cohen’s d 95% CI 17.9, 97). Participants receiving manual therapy in addition to usual care showed gains of 30.1 (9.3, 51.3); effect size 0.55 (16.9, 94). Participants receiving combined therapy and manual therapy in addition to usual care did not meet the a priori threshold for clinical significance (28 points), but were 26.2 (6.1, 46.3) WOMAC points better than usual care only, for a clinically significant effect size of 0.52 (11, 91). The exercise therapy group showed greater mean changes on most physical performance tests than the other groups.
Conclusion: Both exercise physiotherapy and manual physiotherapy provided incremental benefit over usual care alone at 2 years follow-up. Physical performance test outcomes significantly favoured the exercise therapy group.
Background/Purpose: Juvenile dermatomyositis (JDM) affects 3 children/million/year with myositis and skin disease being the typical features. The Pediatric Rheumatology International Trials Organisation (PRINTO) have recently established criteria to classify JDM patients who are clinically inactive by meeting at least 3 out of the following 4 conditions – Creatine Kinase (CK) ≤150 U/L, Childhood Miositis Assessment Score (CMAS) ≥48, Manual Muscle Testing of 8 groups (MMT8) ≥78 and physician global Visual Analogue Scale (PGA) ≤0.2. CK, CMAS and MMT8 all measure muscle involvement, only PGA includes skin or other organ involvement. The hypothesis that these criteria may fail to detect patients who have active skin disease but normal muscle parameters was tested. The aim was to demonstrate the prevalence of clinically inactive disease in the UK JDM Cohort and Biomarker Study and to identify whether skin disease is still present in these patients on the basis of the PRINTO criteria.

Methods: Data were analysed from children who were recruited and met Bohan-Peter criteria. Data from patient episodes (either a clinic visit or hospital admission) were assessed using the PRINTO criteria. Using the PRINTO rules stipulating 3 of 4 criteria are required, all data entries were divided into 2 groups based on the criterion that was omitted. Each case was analysed to determine whether skin disease was present or absent. Results: 682 data entries (DE) from 321 patients were identified as clinically inactive 235 (37.4%) of these DE (119 patients) met all 4 criteria. 21.2% of DE had skin rash and 10.5% had nailfold changes (Table 1) at the time of assessment. 427 of the total DE (202 patients) met 3 of the 4 criteria. Of these, 320 (79.4%) had clinically inactive based on the 3 muscle criteria (PGA was not met). 61.6% of this group had ongoing skin rash present. Among the 107 remaining DE, which were clinically inactive by 3 criteria of which one was PGA, the frequency of skin changes was lower. The differences between the 3 groups were statistically significant in terms of rash ($\chi^2$ 111.5, $p<0.0001$), nailfold changes ($\chi^2$ 65.5, $p<0.0001$) and calcinosis ($\chi^2$ 22.07, $p<0.0001$).

Table 1: Frequency of skin changes in JDM patients meeting PRINTO criteria (number of episodes, % in brackets)

Conclusion: This study is one of the first to test the PRINTO criteria in a large independent cohort of JDM patients. When clinically inactive disease is defined by “muscle-based” criteria, without PGA, there is a greater frequency of skin disease. As a revision, we propose that PGA should be defined by “muscle-based” criteria, without PGA, there is a greater frequency of skin disease being overlooked in the clinical assessment which included as an essential criterion together with 2 of the 3 muscle criteria. This frequency of skin disease. As a revision, we propose that PGA should be included as an essential criterion together with 2 of the 3 muscle criteria. This frequency of skin disease. As a revision, we propose that PGA should be included as an essential criterion together with 2 of the 3 muscle criteria. This frequency of skin disease. As a revision, we propose that PGA should be included as an essential criterion together with 2 of the 3 muscle criteria.

Predictors of Relapse after Discontinuing Systemic Treatment in Childhood Autoimmune Chronic Uveitis, Gabriele Simonini, Claudia Bracaglia, M. Arcaro Cattalini, Andrea Taddeo, Alice Brambilla, Cinzia Deli Iberio, Denise Pires Marafon, Roberto Caputo and Rolando Cimaz. 1 Anna Meyer Children’s Hospital-University of Firenze, Florence, Italy, 2 Division of Rheumatology, Ospedale Pediatrico Bambino Gesù, IRCCS, Rome, Italy, 3 Institute of Child Health, IRCCS Burlo Garofolo, University of Trieste, Trieste, Italy, 4 Anna Meyer Children’s Hospital, Florence, Italy, 5 Ospedale Pediatrico Bambino Gesù, IRCCS, Roma, Italy.

Background/Purpose: Information regarding the natural clinical history of a child on systemic treatment due to autoimmune chronic uveitis would be helpful in driving duration therapy. Aim of our study was to assess the time on remission after discontinuing systemic therapy in a retrospective, comparative, multi-centre, cohort study of childhood non-infectious chronic uveitis.

Methods: 40 patients (30 F, 10 M; median age: 11.6 years, 31 JIA, 9 Idiopathic Chronic Uveitis (IUCU)) from 4 different paediatric rheumatology centres, with previously refractory, vision threatening, non-infectious inactive uveitis, which discontinued all related treatments for at least 3 months were enrolled. 23 children previously received Methotrexate, 17 TNF inhibitors. Primary outcome was to assess, once remission was achieved, the time on remission up to the first relapse after discontinuing treatment. Time to remission once systemic not-steroid treatment was started, time to steroid discontinuation, number of relapses before achieving remission and time on remission on therapy before discontinuing all treatments were also considered. Statistical Analysis: Mann-Whitney U-test, Wilcoxon signed-rank test for paired samples, c-square tests, and Fisher’s exact test, when appropriate, were used to compare data. Pearson and Spearman correlation tests were used to determine correlation coefficients for different variables. In order to identify predictors of outcome Cox regression model and Kaplan-Meier curves were constructed, each one at mean of enter ed covariates.

Results: Median follow-up time on remission without treatment was 9 months (range 1–59 months). At last available follow-up after 1 year from discontinuation of treatment (49 months, range 15–168), 11/39 (28.2%) children maintained a complete remission over a median period of 18 months. At 49 months of follow-up, 6/18 children with IUCU (75%) compared to 5/31 children with JIA (16.1%) were still on remission without treatment ($p<0.003$). A higher probability of maintaining uveitis remission after discontinuing treatment was shown in IUCU compared to JIA group (Mantel-Cox c2 7.62, $p<0.006$) (Figure). A N A positivity was associated with a higher probability of flare in overall population (Mantel-Cox c2 6.68, $p<0.01$), but not in sub-analysis limited to JIA (Mantel-Cox c2 0.78, $p=0.57$) and IUCU (Mantel-Cox c2 1.18, $p=0.27$). None clinical variable, including time on remission on therapy, total length of treatment, and type of treatment, resulted significant predictors of long-lasting remission without therapy.

Conclusion: Even if limited to a relatively small group in retrospectively study design, our results suggest that type of disease, rather than the type or the length of treatment, can predict different duration of uveitis remission without systemic therapy.

The Health Status of Patients with Juvenile Idiopathic Arthritis (JIA): Significantly Worse than After Transfer from Pediatric to Adult Care. Kirsten M Inden, Jens K Iotsche, Martina Niewerth, Angela Zink, and Gerd Homeff. 1 Charité University Medicine, Berlin, Germany, 2 German Rheumatism Research Center, Berlin, Germany, 3 German Rheumatism Research Centre and Charité University Medicine, Berlin, Germany, 4 A. Klinik Sanit Augustin, Sankt Augustin, Germany.

Background/Purpose: Information regarding the natural clinical history of a child on systemic treatment due to autoimmune chronic uveitis would be helpful in driving duration therapy. Disclosure: G. Simonini, None; C. Bracaglia, None; M. Cattalini, None; A. Taddeo, None; A. Brambilla, None; C. Deli Iberio, None; D. Pires Marafon, None; R. Caputo, None; R. Cimaz, None.
Background/Purpose: A minority of patients with polyarticular JIA enter adulthood in drug free remission. Thus, patients are in need of care beyond adolescence. There is little information how patients' health status changes after discharge from pediatric care. We therefore investigated changes in the patients' health status before and after the transfer from pediatric to adult health care.

Methods: Data from patients were considered who were prospectively followed in the JIA biologic registry BiKeR and in the follow-up register JuMBO for at least two additional years. The last observation in JuMBO (mean 2.6) is less than 2 years after the last observation in BiKeR (mean 4.2). The whole observation period comprised 8.2 vs. 4.5 to 2.1 (mean) years, from enrollment until the last visit in BiKeR, all PROs significantly improved: overall well-being from 4.5 to 2.1 (mean), pain level from 4.6 to 1.9, functional status (CHAQ-score) from 0.75 to 0.35. In contrast to this trend towards a steady improvement in patients' health state in pediatric care, PROs significantly worsened after discharge from pediatric care (p < 0.0001). At the last follow-up in JuMBO, when patients were at the age of 23 years and had a disease duration of 14.2 ys, the mean disease activity was 2.6, pain level 2.8, and overall well-being 2.9. At that time, more patients had an active disease (NRS0: 71 vs. 57%) and reported pain (78 vs. 56%) and restrictions in overall well-being (86 vs. 58%) than at the last visit in pediatric care.

A dual health care providers rated the patients' disease activity at first documentation in JuMBO lower than pediatric rheumatologists at the last visit in pediatric rheumatology care (1.8 vs. 2.1), which is in contrast to patients' self-reports. They also rated the disease activity lower than the patients did at last observation in JuMBO (1.9 vs. 2.6). The correlation between physician and patient scores for disease activity was better during pediatric than adult care (0.56 vs. 0.51).

Conclusion: The state of patients with long-standing JIA significantly worsens after discharge from pediatric care. The reasons for this have to be explored. In addition, there are larger discrepancies between physician- and patient-reported outcomes in adult care than in pediatric care.

2903 Early Outcomes in Pediatric Antineutrophil Cytoplasmic Antibody (ANCA) Associated Vasculitis (AAV). Kimberly Morishita1, Susanne Benseler2, Rae S.M. Yeung3, Dawn Wahezi4, Kenneth N. Schikler5, Erica F. Lawson7, Susan Nielsen8, Sirirat Charuvanij9, Paul J. Foley, Orla Killeen and Emma Jane MacDermott. The National Centre for Paediatric Rheumatology, Dublin, Ireland.

Background/ Purpose: The ‘Arthropathy of Down syndrome’ was first described in 1984. Three decades on we still have limited literature on the clinical & radiological features of this arthritis, despite the fact that it is thought to be 3–6 times more common than Juvenile Idiopathic Arthritis (JIA) in the general paediatric population. Down’s Arthropathy (DA) is rarely recognised at onset, & remains under-diagnosed & largely under-reported in this population group. Ireland has one of the highest Trisomy 21 (T21) birth rates in Europe (1/547), and therefore provides an ideal setting for such a study.

Research Questions
1. What are the clinical & radiological features of DA?
2. Is DA missed, leading to a delay in diagnosis?

Objective
To perform a musculoskeletal examination on children with T21, aged 0–18 years & document:
1. Presence of features to suggest old and/or present arthritis.
2. Radiological findings.

Methods: From May 2013 to September 2014, Children with T21 (aged 0–18 years) were invited to attend a screening clinic. Screening involved completion of a health questionnaire & musculoskeletal examination. Suspected cases of DA were invited to attend the National Centre for Paediatric Rheumatology (NCPR) for investigation, treatment & follow-up as per normal clinical practice.

Results: 370 children with T21 enrolled in the study, 56% M a/e. 17 new cases of DA were detected, only 3 (17.6%) of which were referred with suspected arthritis. In total, 28 children with DA now attend the NCPR for management of their arthritis, the largest cohort ever reported in the literature. We estimate the Point Prevalence of DA in Ireland to be 17–18/1000. For
compared the UK Prevalence of JIA is 1-2/1000. Table 1 compares characteristics of our DA cohort to a JIA comparison group.

</tbody>
</table>

Features of DA - Summary of our findings
- Polymicrobial Rheumatoid Factor negative presentation (69% of DA cohort).
- Finger involvement (77% of DA cohort) - significantly greater proportion than seen in the JIA comparison group.
- Erosive changes noted on X-Ray at presentation (27% of cohort).
- Methotrexate nausea common, but a good response to steroid intra-articular joint injections observed.
- General lack of awareness about the increased risk of arthritis in children with T21.

Conclusion: Children with T21 are at increased risk of developing arthritis, however there is often a delay in diagnosis. Reasons for this are multifactorial and include, failure of the child to express and localise pain, and changes in mobility attributed to the Down syndrome rather than a Rheumatological cause. Early diagnosis & treatment of DA is key to preventing changes in mobility.

The IL-6/Th17 Axis Promotes Autoantibody-Associated Autoimmune Valvular Carditis in Mice. Jennifer L. Auger, Brianna J. Engelson, Yaya Wang, Erik J. Peterson and Bryce A. Binstadt. University of Minnesota, Minneapolis, M N.

Background/Purpose: Autoimmune valvular carditis occurs in patients with systemic lupus erythematosus, rheumatoid arthritis and rheumatic fever, but the pathogenic mechanisms remain incompletely defined. Spontaneous autoimmune valvular carditis develops in the K/BxN T cell receptor transgenic mouse model of autoantibody-dependent inflammatory arthritis. CD4 T helper (Th) cells and macrophages cooperate to promote carditis in this model. We investigated which effector Th cell population was the predominant driver of cardiovascular pathology in K/BxN mice.

Methods: We first used RT-PCR to measure key cytokine transcript levels in cardiac valves of arthritic K/BxN mice and controls. We then used anti-cytokine blocking antibodies and gene knockout mice to determine which Th effector cells and cytokines were most critical for valve inflammation.

Results: We found increased expression of the genes encoding the Th17 differentiation factor IL-6 and IL-17A itself in K/BxN mitral valves relative to controls; IL-4 and IFN-y transcript levels were not different. Antibody blockade of IL-6 or IL-17A reduced the severity of valve inflammation, whereas blocking IL-4 had no effect. Genetic deficiency of IFN-y did not affect carditis severity. K/BxN mice lacking the key Th17 transcription factor ROR-yt had delayed onset of arthritis and were protected from valvular carditis.

Conclusion: Th17 cells are key drivers of autoimmune valvular carditis in K/BxN mice. We suggest a model in which autoantibodies engage Fc receptors on macrophages, leading to IL-6 production, which in turn promotes the differentiation of valve-infiltrating Th17 effector cells. Our results provide new insight into the mechanisms of valvular carditis in systemic autoantibody-mediated rheumatic diseases. More broadly, these findings may help guide the selection of therapies to reduce cardiovascular morbidity and mortality among patients with rheumatoid arthritis and systemic lupus erythematosus.

Systemic Delivery of Short Hairpin RNA Targeting Calcium Release-Activated Calcium Channel 3 Down-Regulates Severity of Collagen-Induced Arthritis. Shuang Liu1, Takeshi Kiyoi2, Shohe Watanabe3 and Kazutaka Meya4a. 1Informational Biomedicine, Ehime University Graduate School of Medicine, Toon-shi, Ehime, Japan, 2Integrated Center for Sciences, Ehime University, Ehime, Japan, 3Japan Community Health Care Organization Uwajima Hospital, Ehime, Japan.

Background/Purpose: In recent years, one widespread and potentially important Ca2+ channel, store-operated Ca2+ release-activated Ca2+ (CRAC) channel is raised in drug discovery for rheumatoid arthritis (RA). Ca2+ entry through CRAC channels drives exocytosis, stimulates mitochondrial metabolism, activates gene expression and promotes cell growth, proliferation, and non-exitable cells. Downregulation of the CRAC channels lead to irregular functions of T cells, B cells and osteoclasts, which contribute to RA pathogenesis. The present study was undertaken to investigate the feasibility and efficiency of partially regulation of the Ca2+ influx via CRAC channel by CRACM3 gene-silencing for the treatment of RA.

Methods: We evaluated the therapeutic potential of CRACM3 gene-silencing by systemic delivery of lentivirus expressing CRACM3-shRNA (Lenti-M3shRNA) in a collagen-induced arthritis (CIA) mouse model. The inflammatory response was assessed by measuring the levels of inflammatory cytokines in joint and serum. The cytokine profile of T cells stimulated with autologen was also determined. Mature osteoclast function was analyzed using sartrate-resistant acid phosphatase (TRAP) staining and pit formation assay.

Results: The intraperitoneal injection (10^6 particles/7 days) of Lenti-M3shRNA was highly effective in treating CIA. Ca2+ influxes in splenocytes, thymocytes, and synovial cells were partially blocked by gene-silencing of CRACM3. CIA mice showed significant regression of the disease after Lenti-M3shRNA treatment. The autoimmune response, which was assessed using self-reactive Th1 cell activity and autoantibody production, was significantly suppressed by M3shRNA administration. Low level of the resorptive capacity in mature osteoclasts was also observed in Lenti-M3shRNA treated CIA mice according to the results of TRAP staining and pit formation assay.

Conclusion: Our findings indicate that in vivo gene-silencing CRACM3 by systemic delivery of Lenti-M3shRNA may have beneficial therapeutic effects on RA. Our findings provide valuable insights into the potential ways that CRACM3 could contribute to RA pathogenesis and support the idea that targeting CRAC channels might offer an effective strategy for the treatment of RA.

Loss of microRNA-146a Exacerbates Inflammatory Arthritis. Victoria Saferding1, Antonia Puchner1, Eljana Goncalvesalves1, Birgit Niedereiter1, Silvia Hayer1, Gernot Schabbauer2, Marije K oenders3, Josef S. Smolen1, Kurt Redlich4 and Stephan Blueml1. 1 Medical University of Vienna, Vienna, Austria, 2 Medical University Vienna, Vienna, Austria, 3 Raboud University Nijmegen Medical Center, Nijmegen, Netherlands.

Background/Purpose: MicroRNA (MiR-) 146a is a key regulator of the innate immune response and has also been shown to suppress cancer development in myeloid cells. Elevated expression of miR-146a has been detected in synovial tissue of rheumatoid arthritis patients, but its role in the development of inflammatory arthritis is yet unknown.

Methods: We induced K/BxN serum transfer arthritis in wild type and miR-146a-/- mice. A second inflammatory arthritis model we crossed miR-146a deficient into hTNFtg mice. Disease severity was assessed clinically and histologically in both arthritis models. Blood of arthritis animals was analyzed by flow cytometry. Serum cytokine levels were measured by Elisa.

Disclosure: S. Liu, None; T. Kiyoi, None; S. Watanabe, None; K. Meya, None
Results: Ablation of miR-146a leads to increased clinical signs of the induced serum transfer arthritides. In line, higher serum levels of the proinflammatory cytokines IL12 and TNF were measured in miR146a deficient mice compared to wt mice. When we crossed miR-146a−/− mice into hTNFtg mice, while detecting no clinical difference between hTNFtg and miR-146a−/− hTNFtg mice, we found a significant increase in circulating CD11b+ myeloid cells as well as CD11c+ dendritic cells in blood of miR-146a−/− hTNFtg mice compared to hTNFtg mice. Even more striking, miR-146a−/− hTNFtg mice displayed a more than twofold increase in local bone destruction which was due to increased generation of osteoclasts in the tarsal joints of the mice. Measuring cytokine levels in serum, we show that IL-1α levels are increased in mice lacking miR-146a.

Conclusion: These data clearly demonstrate a negative regulatory role of the miR-146a in inflammatory arthritis. During arthritis, miR-146a is centrally involved in the regulation of proinflammatory cytokines as well as local bone destruction. These results identify an important anti-inflammatory role of miR-146a, which might possibly be exploited for therapeutic purposes.

Flip Deficiency in Dendritic Cells Promotes Spontaneous Arthritis Mediated by Reduced Treg and Increased Autoreactive CD4+ Cells.

QiQun Huang1, Harris R. Perlman2, Robert Birckett3, Renee E. Doyle3, Deyu Fang3, G. Kenneth Haines5, William H. Robinson5, Syamal K. Datta1, Hyewon Phee2 and Richard M. Popel3. 1Northwestern University Feinberg School of Medicine, Chicago, IL. 2Mount Sinai Hospital School of Medicine, New York, New York, NY. 3VA Palo Alto Health Care System and Stanford University, Palo Alto, CA. 4Northwestern University Feinberg School of Medicine, Chicago, IL.

Background/Purpose: Flip (CFLR) has been identified as a rheumatoid arthritis (RA) risk allele and is important in preventing death receptor mediated apoptosis of dendritic cells (DCs). To examine the in vivo role of Flip in DCs in maintaining immune homeostasis, mice deficient in Flip in conventional DCs were generated (DC-Flip−/−). The DC-Flip−/− mice spontaneously develop erosive, inflammatory peripheral arthritis, resembling rheumatoid arthritis (RA). These studies were conducted to define the mechanisms that contribute to the development of arthritis in these mice.

Methods: Immune cell phenotyping was performed by flow cytometry. DC function was examined by antigen presentation and T regulatory cell (Treg) induction. Thymic T cell development, selection and tolerance were examined. T cell autoreactivity was determined by the syngeneic mixed lymphocyte response in vitro and by adoptive transfer into vivo, monitored by dilution labeling of T cells. Treg function was examined by suppression of CD4+ T cell proliferation. Autoantibodies to joint components were identified by immunoblotting. DC-Flip−/− mice were crossed with Rag−/− to generate DC-Flip-KO/Rag−/− double mutant lines and arthritis was evaluated. All data are analyzed comparing indicated genotypes in age and gender matched groups.

Results: CD11cCre mediated Flip deficiency resulted in consistent reduction of the CD11c+CD8α− subset of DCs in central and peripheral lymphoid organs but not in the subset of DCs. No defects in the DCs were identified, however, increased autoreactive CD4+ T cells and plasmablasts are identified in the lymph nodes draining the inflamed joints, and both were positively correlated with the severity of arthritis. The DC-Flip−/− mice possessed autoantibodies specific for joint components. Further, Tregs were reduced in the thymus and spleen of DC-Flip−/− mice in a setting of lymphopenia. In addition, the number of Tregs in the spleen inversely correlated with the severity of the arthritis and adoptive transfer of Tregs ameliorated joint inflammation. DCs isolated from the DC-Flip−/− mice effectively presented antigen but were deficient in promoting the induction of Tregs. Supporting the role of T and B cells, DC-Flip−/−/Rag−/− mice, which lack both of T and B cells, develop significantly milder and self-limiting arthritis compared with the DC-Flip−/−/Rag−/− mice.

Conclusion: Flip plays a key role in the survival of the CD8α+CD11c+ DC subset in vivo. The loss of this subset impairs the generation and/or maintenance of Tregs, which in turn permits the expansion of autoreactive CD4+ T cells and autoantibody producing B cells, resulting in autoimmune arthritis. Our observations suggest that the DC-Flip-KO mouse is a novel model of RA that may provide important insights and permit in depth investigation of the pathogenesis of RA.

Tolerogenic Splenic IDO+ Dendritic Cells from the Mice Treated with Induced-Treg Cells Could Suppress Collagen-Induced Arthritis. Jie Yang1, Hushua Fan2 and Hejian Zou3. 1Division of Rheumatology, Huashan Hospital, Fudan University, Shanghai 200040, China. Shanghai, China. 2Blood Engineering Laboratory, Shanghai Blood Center, Shanghai 200051, China. Shanghai, China.

Background/Purpose: As well known, Foxp3+ regulatory T cells play a crucial role in maintaining immune tolerance. It was reported that TGF-β induced Tregs (iTregs) could retain Foxp3 expression and immune suppressive activity in the collagen-induced arthritis (CIA). However, the mechanisms whereby iTregs suppressed immune response, especially the interplay between iTregs and DCs in vivo, remained incompletely understood. In this study, whether splenic DCs were involved in iTreg-based suppression and how these DCs further inhibited CIA were determined.

Methods: In vitro, iTregs were induced by TGF-β and adoptive transferred into established CIA mice. After 7 days, splenic CD11c+ DCs were isolated, termed DC-ITreg. The phenotype, the expression of cytokines and inhibitory associated molecules, the immunogenicity and the suppression on CD4+CD8+ T cell differentiation of DC-ITreg were assessed. To determine the suppression in vivo, 5×10⁵ of DC-ITreg were re-infused into the new CIA mice. Clinical and histopathologic scores, cytokine and anti-CII antibody secretion in serum were analyzed. And it also was determined the expression of Foxp3 and function of Tregs after IDO-DCs transferred. Additionally, the role of IDO in the inhibitory effect of DC-ITreg was determined by 1-MT blocking in vitro in CIA mice.

Results: After iTregs adoptive transferred, isolated DC-ITreg exhibited a series of tolerogenic characteristics. Compared with splenic DCs isolated from CIA mice (DCcIA), DC-ITreg expressed obviously lower levels of MHC molecule (IA-IE) and co-stimulatory molecules (CD80, CD86 and CD40). And IL-12p40 and IL-6 production by DC-ITreg were negligible, while high levels of IL-10 and TGF-β were expressed; especially enhanced level of IDO by DC-ITreg was detected, and CD11b+ DCs were found as a major contributor of IDO expression in iTreg-treated CIA mice. In the proliferation assay, DC-ITreg showed the poor ability to expand effector T cells and had the effective inhibitory potency. Meanwhile, after CD11b+ IDO−DC-ITreg re-infused, a remarkable anti-arthritis activity, improved clinical scores and histological end-points were found. Also, serological levels of TNF-α, IL-6, IL-17 and anti-CII antibodies showed significantly low and TGF-β production was high in the DC-ITreg-treated group. Conversely, DCcIA could not suppress CIA completely. And IDO-DCs could induce the generation and proliferation of functional Foxp3+ Tregs in vitro and in CIA mice. Moreover, DCcIA lost the inhibitory ability on CIA when they pretreated 1-MT.

Conclusion: These findings suggested that iTregs could inhibit CIA via tolerogenic splenic DCs formation. These tolerogenic splenic DCs could further effectively dampen the severity and progression of CIA in the IDO-dependent manner, which was associated with modulation of inflammatory cytokine and anti-CII antibody secretion and induction of new iTregs. Thus, the potential therapeutic effect of iTreg in CIA and RA is likely to be maintained, even enlarged by their effects on DCs in vivo.

Tofacitinib Facilitates the Expansion of Myeloid-Derived Suppressor Cells and Ameliorates Arthritis in SKG Mice. Keisuke Nishimura, Jun Saegusa, Fumichika Matsuki, Kengo A Kashii, Goichi Kageyama and Akio Morinobu. Kobe University Graduate School of Medicine, Kobe, Japan.

Background/Purpose: Myeloid-derived suppressor cells (MDSCs) are a heterogeneous population of cells that are characterized by the co-expression of Gr1 and CD11b in mice. MDSCs suppress T cell responses by producing arginase I (Arg I) and inducible nitric oxide synthase (iNOS). Tofacitinib is a Janus kinase (JAK) inhibitor that inhibits JAK1 and JAK3. Tofacitinib currently represents a novel therapeutic for treating rheumatoid arthritis. However, the anti-rheumatic effects of tofacitinib, especially its influence on...
myeloid cells, are not fully understood. The aim of this study was to evaluate the effects of the Janus kinase inhibitor tofacitinib on MDSCs in a mouse model of rheumatoid arthritis.

**Methods:** Arthritis was induced in SKG mice by zymosan A (ZyA) injection. MDSCs isolated from the bone marrow (BM) of donor arthritic SKG mice were adoptively transferred to recipient arthritic mice. In a separate experiment, tofacitinib was administered to SKG mice arthritic mice subcutaneously via osmotic pump, in some cases followed by injection of an anti-Gr1 monoclonal antibody (mAb). BM cells from untreated mice were cultured for 5 days with granulocyte/macrophage colony-stimulating factor (GM-CSF), with or without tofacitinib, and then analyzed by flow cytometry.

**Results:** The BM and spleens of ZyA-treated mice contained increased numbers of CD11b^+Gr1^+ MDSCs, whereas polymorphonuclear (PMN)-MDSCs (CD11b^+Ly6G^-Ly6Chi^low^) were significantly increased in the spleen of ZyA-treated mice. The number of monocytic-MDSCs (CD11b^+Ly6G^-Ly6Chi^low^) was also significantly increased in the BM of ZyA-treated mice, although they represented only a small proportion of the BM cells. The BM cells from ZyA-treated SKG mice also expressed higher levels of INOS and Arg I compared to untreated SKG mice. The adoptive transfer of MDSCs to recipient arthritic mice reduced disease severity compared to the untreated controls. Continuous administration of tofacitinib significantly ameliorated the arthritic scores of SKG mice. Tofacitinib treatment significantly increased the numbers of total- and PMN-MDSCs in the BM of arthritic mice. Furthermore, the anti-arthritic effect of tofacitinib was abrogated when MDSCs were depleted by anti-Gr1 mAb. In vitro, tofacitinib facilitated the differentiation of BM cells to MDSCs, and inhibited their differentiation to dendritic cells. Moreover, tofacitinib-treated BM cells were incapable of enhancing T cell proliferation, compared to mock-treated BM cells.

**Conclusion:** MDSCs play crucial roles in the regulation of SKG arthritis, and a JAK inhibitor, tofacitinib, enhances their expansion. Our results suggest a novel mode of anti-arthritic action for tofacitinib and a critical role for JAKs in the differentiation of MDSCs.

**Clinical Outcomes of Early RA after 7 Years - Does T2T Approach Overcome Delay of Therapy?**

**Tuulikki Sokka,1 Hannu Kautiainen,2 Tuomas Rannio,3 Juha Asikainen1 and Pekka Hannonen1. 1Jyväskylä Central Hospital, Jyväskylä, Finland, 2Medcare Oy, Äänekoski, Finland, 3Kuopio University Hospital, Kuopio, Finland.**

**Background/Purpose:** Early vs. delayed referral/start of therapy within 3–4 months has been shown beneficial for outcomes in rheumatoid arthritis (RA) (Lard et al. A.M.J Med 2003, Gremese et al. ARD 2013, Ehrmann Feldman et al. Rheumatology 2013). However, in a real world setting, this applies for a minority of RA patients. In the FIN-RAco study, a delay of 4 months significantly influenced a 2-year remission rate in the monotherapy arm (remission rate was 11% vs 35%) while in the combination arm, 42% were in remission regardless of a delay indicating that early intensive therapy may overcome a delay (Möttönen et al. A&R 2002). Therefore, our aim was to study whether a delay of starting therapy in early RA affects long-term outcomes in a clinic with T2T approach including preferring methotrexate based combinations over monotherapy, long-term low dose glucocorticoids over bridging, intra articular glucocorticoid injections to all swollen joints at every visit, patient education by specialist nurses, and routine monitoring including disease activity and self-reported outcomes.

**Methods:** A clinical database in a district of 275,000 population was analyzed for patients with a new diagnosis of RA in 1993-2013. Variables included demographics, clinical course, follow-up, medication, and the date of first symptoms of RA, a question which was asked from the patient at the first visit and recorded in the database. Duration of symptoms (delay) at initiation of therapy was categorized as 0–3mo, 4–6mo, 7–12mo, 13–24mo, and >2yr. Outcome variables and medication data were available in 60–68% of patients at a mean of 7.3 years after diagnosis.

**Results:** In 1993–2013, 2374 patients (mean age 56yr, 67%F; 59%RF/CCP+) were diagnosed and treatment started with a median delay of 5.4mo in 2005 to 7.4 in 2003 with no trend of delay over years. Existing musculoskeletal disease and younger age were associated with longer delay, adjusted for sero+/−, gender, and year of diagnosis. Overall, 32%, 24%, 24%, 10%, and 10% of patients had a delay of 0–3mo, 4–6mo, 7–12mo, 13–24mo, and >2yr, respectively (in 98 patients delay data was missing). After a mean follow-up of 7 years, the mean swollen and tender joint counts (SJC28) was <1. The mean ESR and CRP were normal, symptom level was low, functional capacity well maintained, and 66% of patients met the DAS28 remission (Table). No significant differences in outcomes and treatments were observed between the delay groups.

**Conclusion:** Clinical outcomes were good after 7 years in patients with early RA who were treated extensively using a T2T approach, including 66% of patients in DAS28 remission. Delay of treatment start did not influence outcomes in this clinic. Further analyses will include radiographic outcomes and work disability.

**Disclosure:** T. Sokka, None; H. Kautiainen, None; T. Rannio, None; J. Asikainen, None; P. Hannonen, None.
of 12.4. An internet-based data entry and management system (IDEMS) was designed to automate calculation of the DAS and alert sites to the requirement for treatment change. If a treatment change was not made a reason for that decision was required. RA outcomes (HAQ, RAID, SF36) and attainment of remission (DAS, CDAS, SDAI, ACR Boolean) were compared by adherence to T2T and according to treatment category (DMARD, anti-TNF).

**Results:** As of June 2014, 500 patients have been recruited of whom 172 have completed at least 15 months follow-up. Adherence to T2T was 52% and non-adherence 42% for at least 1 study visit (T2T failure visit). Reasons for non-adherence were: physician decision that current treatment was acceptable (69%), physician decision (other) (14%), patient decision (9%), physician decision due to concern for adverse event (2%), other non-specific (6%). Starting at 6 months of follow-up and continuing to diverge though 15 months, all outcomes were superior in T2T adherent patients: improvement in SJC/TJC, patient/physician global, HAQ, RAID, SF36. Remission at 15 months follow-up was more frequent in T2T adherent patients at 75% (DAS), 41% (CDAS), 41% (SDAI), 40% (ACR Boolean) compared to non-adherent patients at 30% (DAS), 12% (CDAS), 13% (SDAI), 15% (ACR Boolean) irrespective of therapy (standard DMARD, anti-TNF).

**Conclusions:** Adherence to T2T is associated with consistent improvement in RA outcomes and increased rates of remission. However, there remains a substantial gap in implementation even in protocol-specified clinical settings.
was higher in initially non-radiographic arthritis patients (3.3 erosions/year vs. 0.4, resp., p < 0.0001).

Conclusion: The clinical and radiographic course of early undifferentiated arthritis under treatment was not dependent on the presence of erosions in 3 or more joints (i.e. the definition of radiographic disease by the EULAR taskforce) at diagnosis in our cohort.

Effects of Methotrexate on Anti-TNF Treatment in Rheumatoid Arthritis: An In-depth Analysis of a Prospective Observational Study with Adalimumab.

Marc Schmalzing1, Frank Behrens2, Eva C. Scharbatke3, Michaela Koehm3, Bianca Wittig4, Gerd Greger 5, Harald Burkhardt2, and Hans-Peter Tony1.

1University of Würzburg, Würzburg, Germany, 2Goethe-University Frankfurt, Frankfurt, Germany, 3Fraunhofer Institute for Molecular Biology and Applied Ecology IML, Project Group Translational Medicine & Pharmacology TMP, Frankfurt/Main, Germany, 4Abbvie Deutschland GmbH & Co. KG, Wiesbaden, Germany, 5AbbVie GmbH & Co KG, Wiesbaden, Germany.

Background/Purpose: Methotrexate (MTX) is currently the most frequently used drug in the treatment of rheumatoid arthritis (RA). MTX co-medication can improve the therapeutic benefit of adalimumab (ADA) in biologic-naive RA patients. However, the impact of concomitant MTX has not been fully characterized in patients pretreated with biologics. Similarly, the influence of adding MTX to established ADA monotherapy has not been fully characterized.

Methods: We analyzed data from a large German multicenter, prospective, observational study of patients with active RA who are treated with ADA during routine clinical care. The effect of therapy on mean DAS28 scores was evaluated at baseline (month 0) and at months 3, 6, and 12 for patients receiving continuous ADA monotherapy, continuous ADA + MTX combination therapy, and MTX added to ADA therapy at 6 months (ADA monotherapy for the first 6 months and ADA + MTX combination therapy for months 6–12). Subgroup analyses for ADA monotherapy vs ADA + MTX were performed on biologic-naive versus biologic-experienced patients. Stepwise forward and backward regression analyses were performed for identifying significant predictors.

Results: Combination therapy with ADA + MTX resulted in lower mean DAS28 scores at month 12 and a significant reduction in ADA scores from baseline than ADA monotherapy (Table). DAS28 improvements in patients who began the observation period on ADA monotherapy and added MTX at month 6 were similar to those receiving ADA + MTX continuously for 12 months. Subgroup analysis by prior biologic therapy indicated that both biologic-naive and biologic-experienced patients achieved lower mean DAS28 scores with ADA + MTX than with ADA monotherapy (p < 0.0001). However, patients treated previously with biologics did not show as much improvement in DAS28 scores as biologic-naive patients, irrespective of MTX use.

Conclusion: Adding MTX to ADA monotherapy at month 6 resulted in DAS28 decreases similar to those observed with continuous ADA + MTX therapy, although patient numbers were small. Both biologic-naive and biologic-experienced patients achieved lower DAS28 scores with ADA + MTX than with ADA monotherapy. These findings support the addition of MTX to ADA therapy for all patient populations.

Table 1. Effect of concomitant MTX on therapeutic response during ADA-therapy.

Effects of Exercise on Body Composition, Cardiovascular Fitness, Muscle Strength, and Cognition in Patients with Rheumatoid Arthritis: A Randomised Controlled Trial of a Patient-Specific Exercise Programme.

Maha Azeem1, Ciara Clancy2, Tom O’Dwyer3, Fiona Wilson4, and Gaye Cunname5.

1St James’s Hospital and Trinity College Dublin, Dublin, Ireland; 2Trinity College Dublin, Dublin, Ireland.

Background/Purpose: Rheumatoid Arthritis (RA) patients have lower levels of physical activity compared to their non-RA counterparts. Large proportions of patients with RA are overweight or obese, and exhibit poor cardio-respiratory fitness and reduced muscle strength. These factors have been associated with poor function and increased mortality. A less well studied but important co-morbidity that affects RA patients is cognitive impairment, which can have a negative impact on patients’ ability to manage their disease. We aimed to investigate the effects of a specifically designed exercise programme on body composition, aerobic capacity, muscle strength and cognition in RA patients.

Methods: Sixty-six patients with RA were randomised on a 1:1 case:control ratio. A assessments included body composition (waist circumference), fitness (VO2 max), muscle strength (hand-grip) and cognitive testing (Montreal Cognitive Assessment), in addition to disease related measures. Patients in the intervention group were enrolled for a three-month exercise programme. The control group received standard care.

Results: Twenty-eight cases and 24 controls attended for baseline testing. Seven patients were subsequently lost to follow up (4 cases and 3 controls). There were significant improvements in several measured outcomes in the intervention group compared to controls after three months. Median waist circumference was significantly reduced in cases, with median value 94.0 cm (range 67.3–124.5) at 0 months, compared to 91.4 cm (range 66.0–124.5) at 3 months, (2.8% reduction, p < 0.0001). A aerobic capacity, as measured by VO2max, for cases was 23.2 ml/kg/min at 0 months compared to 27.6 ml/kg/min at 3 months (19% increase, p = 0.002). Median right grip strength was 12kg (0–23) at 0 months, compared to 13kg (0–30) at 3 months (8.3% increase, p = 0.025). For left grip strength, the median value was 8kg (0–20) at 0 months, compared to 10kg (0–32) at 3 months (25% increase, p = 0.005). There was a significant improvement in cognitive function for cases, with median Montreal Cognitive Assessment value 25.5 (20–30) at 0 months compared to 28.0 (22–30) at 3 months (10% increase, p = 0.001). There was also a significant reduction in C-reactive protein (median 2.8, range 1.0–27.4 at 0 months compared to 1.9, 1.0–18.4, at 3 months, equating to a reduction of 32.1%, p = 0.025). Fatigue scores, measured by Global Fatigue Index were reduced from median 13.2 (range 6.4–34.1) at 0 months, to 10.9 (6.5–37.5) at 3 months (p = 0.047). There was a significant reduction in trunk fat at 3 months (median 37.3, range 16.3–56.9) compared to 36.2, range 16.3–56.5 (p = 0.004). For all above measures, there was no significant difference in median control values at 3 months.

Conclusion: There are significant benefits associated with physical activity for both general health and RA-related parameters, as evidenced by the current data. This study has demonstrated for the first time that exercise has a significant impact on cognitive function in RA. We can conclude that physical activity is safe and effective in RA patients and should be a vital component of management protocols.

Inhibition of PADA4 Activity and the Formation of Neutrophil Extracellular Traps Via PTPN22, but Not Its Rheumatoid Arthritis-Prone W620 Variant. I-Cheng Ho1, Hui-Hsin Chang1, Nishant Dwivedi1, Hsiao-Wei Tsa2 and Anthony Nicholas2. 1Brigham and Women's Hospital, Boston, MA; 2University of Alabama at Birmingham, Birmingham, AL.

Background/Purpose: One unique feature of rheumatoid arthritis (RA) is the presence of anti-citrullinated protein antibodies (ACPAs). Protein citrullination, a process mediated by peptidyl arginine deiminases, such as PADA4, not only yields antigens recognized by ACPAs but also contributes to RA through several other mechanisms including promotion of neutrophil extracellular traps (NET) formation. A C-to-T single nucleotide polymorphism (SNP) located at position 1856 of human PTPN22, a protein tyrosine phosphatase, carries an odds ratio of 2–3 and, together with HLA alleles, contributes to RA independently of its phosphatase activity. Conversion of the R620 to tryptophan increases the risk of ACPA – a key feature of RA. Here we postulate a role for PTPN22 in the formation of neutrophil extracellular traps.

Methods: We quantified the amount of citrullinated proteins in wild type and PTPN22-deficient cells, as well as PBMC from healthy donors carrying or not carrying the risk T allele was examined with Western blotting using F95 antibody and anti-citrullinated histone H3. Co-immunoprecipitation was used to examine the physical interaction between PTPN22 and PADA4. The formation of neutrophil extracellular traps was analyzed with Sy-tox uptake and immunocytochemistry.

Results: Impaired expression of PTPN22 resulted in hypercitrullination in mouse and human immune cells. This effect was partly mediated by PADA4. PTPN22 did not regulate the expression or tyrosine phosphorylation of PADA4. Instead, PTPN22 physically interacted with and suppressed the activity of PADA4 independently of its phosphatase activity. Conversion of the R620 to a tryptophan disrupted the interaction between PTPN22 and PADA4, and completely ablated the ability of PTPN22 to suppress protein citrullination. Accordingly, the risk T allele is associated with hypercitrullination in PBMC and heightened propensity to form NET in healthy donors.

Conclusion: PTPN22 is a natural inhibitor of PADA4, and the R620 is critical for this non-phosphatase function of PTPN22. The C1858T-mediated conversion of R620 to tryptophan increases the risk of ACPA in RA through hypercitrullination and heightened propensity to form NET. Our data also identify a novel pathway regulating PAD activity and establish a molecular connection between the two RA risk genes PTPN22 and PADA4.

heart development (LBH). LBH is a conserved putative protein with largely unknown functions. 

Methods: FLS cultures were established from RA and OA synovial tissues from joint replacement surgery. Gene expression was measured by qPCR. LBH gene expression was silenced using siRNA (mean 91% decrease) or over-expressed (mean 13 fold increase) using an LBH expression vector. Differentially expressed genes of 4 RA FLS lines with modified LBH expression were determined by microarray. The affected pathways were identified using Ingenuity Pathway Analysis. Expression of modified (silenced or over-expressed) gene expression was assessed by cell migration (scratch-wound assay), cell growth (MTT), apoptosis (caspase 3/7 activity) and TNF-stimulated gene expression.

Results: LBH is constitutively expressed in RA FLS as determined by qPCR. LBH gene expression was significantly increased LBH mRNA by 5.0 ± 1.0 fold (P = 0.02) and PDGF-BB (0.1 ng/ml, 12 hr) significantly decreased LBH mRNA expression by 5.7 ± 1.7 fold (P = 0.04). Stimulating FLS with TNF, Wnt3a or Wnt 5a had no effect on LBH gene expression. LBH was then knocked down using siRNA, with no effects on cell migration or TNF-induced MMP3 or IL-6 expression. To determine potential functions, microarrays were performed using LBH-deficient FLS. Pathway analysis of gene expression profiles in LBH low compared to control FLS identified "Cellular growth and proliferation" as the most significantly enriched pathway. Therefore, we performed cell growth assays. LBH deficiency increased FLS proliferation by 92 ± 13% (P = 0.018). LBH did not alter apoptosis. 

Conclusion: We identified LBH as a candidate gene for RA by integrating multiple omics datasets. Microarray experiments focused our attention on cell growth as a potential LBH-regulated function, and this was confirmed using functional assays. Furthermore, the gene is highly regulated by growth factors that modulate the cell cycle. The data suggest that LBH contributes to synovial intimal hyperplasia and joint damage in RA.

Contraceptive Factors Are Associated with Serum Antibodies to Citrullinated Protein Antigens in Women at Elevated Risk for Future Rheumatoid Arthritis. Sonia K. Khatte1, Mark C. Parish2, Maria L. Eser3, Jason R. Kollenbach4, Ryan W. Gan5, Michael H. Weisman6, James R. O’Dell7, Ted R. M. Kik2, Richard M. Keating8, Peter K. Gregersen9, Jane H. Buckner9, V. Michael Holers10, Kevin D. Deane11, Jill M. Norris12 and M. Kristen Demoruelle13. 1University of Colorado School of Medicine, Aurora, CO, 2Colorado School of Public Health, Aurora, CO, 3Cedars-Sinai Medical Center, Los Angeles, CA, 4Veteran Affairs Nebraska Western Iowa Health Care System and University of Nebraska Medical Center, Omaha, NE, 5Omaha VA Medical Center and University of Nebraska Medical Center, Omaha, NE, 6Scripps Clinic, La Jolla, CA, 7Feinstein Institute for Medical Research, Manhasset, NY, 8Benaroya Research Institute at Virginia Mason, Seattle, WA.

Background/Purpose: The preclinical period of rheumatoid arthritis (RA) development is characterized by elevations of serum RA-related autoantibodies (Abs) including Abs to citrullinated protein antigens (ACPA) and rheumatoid factor (RF). Serum ACPAs are highly predictive of future inflammatory arthritis (IA) classifiable as RA, and recent data suggesting that ACPAs are directly pathogenic in joint disease highlight the need to understand the etiology of ACPA development. In addition, it remains unknown why RA disproportionately impacts women compared to men, and data suggest hormonal factors may influence the risk of developing RA. Importantly, prior data from our group identified that oral contraceptive pill (OCP) use was associated with a decreased risk for RF positivity in the absence of IA (Bhatia 2007). Therefore, we hypothesize that contraceptive factors will be associated with serum ACPA positivity among arthritis-free women at increased risk for RA.

Methods: In the Studies of the Etiology of RA (SERA) project, 1243 first degree relatives (FDR) of probands with RA were enrolled who are women. Of these FDRs, we studied women who at their baseline visit had serum ELISA testing for ACPA using anti-CCP3.1 (IgG/IgA, INOVA) and a detailed prior contraceptive and pregnancy history obtained using a standardized questionnaire (N = 336). To avoid familial correlation, we also randomly selected only one subject per family; therefore, our final analyses included 297 FDRs. All subjects were without clinical IA at the time of serum testing. In cross-section, associations of ACPA and subject factors were analyzed using chi-squared and logistic regression.

Results: In multivariate analyses, prior use of OCPs was associated with a decreased risk of serum ACPA positivity (OR = 0.34; 95% CI 0.15–0.79; adjusted for age, race and smoking). In addition, there was an increased risk of ACPA positivity in women who had a history of intrauterine device (IUD) use (OR = 2.68; 95% CI 1.11–6.47; adjusted for age, race and smoking). ACPA(+) FDRs were slightly older than ACPA(−) FDRs, but were similar in race, smoking and shared epitope status (Table). No significant association was seen between ACPA positivity and pregnancy or breastfeeding.

Conclusion: Prior OCP use was associated with a decreased risk of ACPA positivity in these FDRs, and these results are in line with our prior findings. OCP use associated with a decreased risk of RF positivity. Of interest was the association of an increased risk of ACPA positivity with IUD use. While the mechanisms that link contraceptive factors to ACPA generation are unknown, unlike OCPs, IUDs have been shown to generate endometrial inflammatory responses. Therefore, the association of IUD use and ACPA suggest that IUD-induced endometrial inflammation may be a potential mucosal trigger of RA-related Abs. Mechanisms by which OCPs could protect and IUDs could increase risk for RA-related autoimmunity need further study.

Table: Association of Single Nucleotide Polymorphisms of PADI4 Gene with Susceptibility to Rheumatoid Arthritis-Related Lung Disease. Seoong-Wook Kang, Seung-Taek Song, Song Soo Kim, Ji Youn Kim, So Yoon Lee, Si-Jin Yoo, In-Seol Yoo, Jinhyun Kim and Seung-Cheol Shim. Chungnam National University School of Medicine, Daejeon, South Korea.

Background/Purpose: Rheumatoid arthritis (RA) causes a myriad of pulmonary complications, including bronchiolitis and bronchiectasis, pleuritis, and interstitial lung disease (ILD). Recently, several studies have shown the association of rheumatoid arthritis-related lung disease (RA-LD) with the high titers of rheumatoid factor (RF) and anti-citrullinated protein antibodies (ACPAs) which are the most specific serologic marker for RA. Single nucleotide polymorphisms (SNPs) in a citrullinating (or deiminating) enzyme, peptidyl arginine deiminase type IV (PADI4) have been reproducibly associated with RA susceptibility in several populations.

The aim of the present study is to investigate if the SNPs in PADI4 gene are associated with RA-LD.

2922
studies are warranted to clarify the mechanisms by which SNPs in the PADI4 gene are associated with susceptibility to RA-LD. Further, statistical differences were seen between RA patients with and those without LD with respect to sex, smoking history, anti-Ro antibody, and those without LD with respect to sex, smoking history, anti-Ro antibody, and use of DMARDs.

Conclusion: Our results suggest that SNPs and genotypes in exon-3 (padi4_92) of PADI4 are associated with susceptibility to RA-LD. Further studies are warranted to clarify the mechanisms by which SNPs in the PADI4 gene affect the development of RA-LD.

Values are the number (%), †; (mean ± standard deviation). A total of 103 consecutive RA patients, who satisfied the 1987 American College of Rheumatology classification criteria, were genotyped for two nonsynonymous (padi4_89 and padi4_92) and one synonymous (padi4_104) SNPs in PADI4. RA-LD was diagnosed using high-resolution computed tomography of the chest. The following data were collected from medical records: Age, sex, disease duration, smoking history, use of disease-modifying anti-rheumatic drugs (DMARDs), RF, and ACPA. We used the t-test for continuous variables and the chi-square or Fisher’s exact test for categorical variables. Multivariate logistic regression analysis was performed to assess the relationship between the SNPs in the PADI4 gene and RA-LD. Results: Of the 103 RA patients, 8 (7.8%) had interstitial lung disease (ILD) and 33 (32.0%) had small airway disease (AD). Higher titers of ACPA (≥80 U/mL; p = 0.022) and RF (≥ULN × 3; p = 0.008) were significantly associated with susceptibility to RA-LD (Table 1). SNPs and genotypes in exon-3 (padi4_92) of PADI4 showed significant association with susceptibility to RA-LD (p = 0.004, respectively) (Table 2). No statistically significant differences were seen between RA patients with LD and those without LD with respect to sex, smoking history, anti-Ro antibody, and use of DMARDs.

Conclusion: Our results suggest that SNPs and genotypes in exon-3 (padi4_92) of PADI4 are associated with susceptibility to RA-LD. Further studies are warranted to clarify the mechanisms by which SNPs in the PADI4 gene affect the development of RA-LD.

Clinical Utility of Random Anti-TNF Drug Level Testing and Measurement of Anti-Drug Antibodies on Long-Term Treatment Response in Rheumatoid Arthritis. M. Eghna\textsuperscript{1} Jani, H. Chinyo\textsuperscript{1}, R. B. Warren\textsuperscript{1}, C. M. Griffiths\textsuperscript{1}, A. W. Morgan\textsuperscript{1}, A. G. Wilson\textsuperscript{2}, K. M. Hyrich\textsuperscript{1}, J. Isaacs\textsuperscript{1}, D. Plant\textsuperscript{1} and A. Barton\textsuperscript{1}.\textsuperscript{1} Centre for Musculoskeletal Research, University of Manchester, Manchester, United Kingdom, \textsuperscript{2}Dermatology Centre, University of Manchester, Manchester, United Kingdom, \textsuperscript{3}University of Leeds, Leeds, United Kingdom, \textsuperscript{4}University College Dublin, Dublin, Ireland, \textsuperscript{5}Institute of Cellular Medicine, University of Newcastle, Newcastle, United Kingdom, \textsuperscript{6}NHRI Manchester Musculoskeletal Biomedical Research Unit, Manchester Academic Health Science Centre, Manchester, United Kingdom.

Background/ Purpose: Up to 40% of RA patients on anti-TNF treatment fail to respond either due to primary inefficacy or loss of response. One explanation is immunogenicity leading to the development of anti-drug antibodies (ADA) and low drug levels, however the clinical utility of pharmacological monitoring is debated. One challenge is the practicality of obtaining trough drug levels in patients and the impact that would have on service delivery. Our aim was to evaluate whether the presence of ADA and/or non-trough drug levels may predict treatment response in patients with RA treated with anti-TNF drugs.

Methods: 391 patients were selected from the Biologics in RA Genetics and Genomics Study Syndicate prospective cohort (n=160 adalimumab (ADL); n=171 etanercept (ETA)). Serum samples were collected at 3, 6 and 12 months following initiation of therapy. ADAs were measured using RIA and drug levels using ELISA assays at 3, 6 and 12 months. Disease activity (DAS28) scores were measured at each visit. Multiple linear regression, logistic regression, generalised estimating equation and ROC curves were used to test the association and predictive value of ADA and/or non-trough drug levels on treatment response as assessed by the change in DAS28 score between pre-treatment and 12 months post-treatment (DAS28).

Results: 835 serial samples were suitable for pharmacological testing (n=414 ADL; n=421 ETA). Mean age: 56 ± 13 years; 75% female; baseline DAS28 score 5.9 ± 3.8; median BMI 27.5 (IQR 23.6–32.3). 85% were on a DMARD (56% MTX). ADAs to ADL were detected in 24.8% (31/125 patients at ≥1 time points by 12 months) and in none of the ETA patients. The presence of ADAs was significantly associated with lower ADL drug levels (ADAb titres > 100 AU p = 0.0041; Spearman’s rho = 0.06). At 3 months, ADAb formation and low ADL levels were a significant predictor of no EULAR response at 12 months (ROC curve analysis, area under curve (AUC) 0.71, 95% confidence intervals (CI) 0.57–0.85). Patients who developed ADAs received lower median doses of concomitant MTX therapy (15mg/week [IQR 10–20]) and had longer disease duration (14.0 years [6.7–19.4]) vs. patients who did not (20mg/week [15–20] p = 0.01; [7.7 years [3.6–16.0]] p = 0.03). ADL drug level was the most significant independent predictor of DAS28 at all time points after adjusting for confounders (p = 0.003, regression coefficient (RC) 0.12; CI: 0.06–0.18). Patients on ETA with higher drug levels (≥15µg/ml) were more likely to achieve a good EULAR response than patients with sub-therapeutic levels (<10µg/ml; p = 0.01). However low ETA levels at 3 months were not a significant predictor of no EULAR response at 12 months (AUC 0.51; CI: 0.41–0.61). BMI was the strongest predictor of low drug levels (ETA, p < 0.001, RC = 5.97; CI = 0.32 to 3.19; ADL, p = 0.001, RC = 3.86; CI = 0.57 to 2.00). Patients with a BMI ≥ 30 had significantly lower drug levels compared to those with a BMI < 30 in both ADL and ETA cohorts (p < 0.01).

Conclusion: Pharmacological testing in anti-TNF initiated patients is clinically useful even in the absence of trough levels. At 3 months ADAb formation and low ADL drug levels are a significant predictor for poor treatment response at 12 months. Patients with a BMI ≤ 30 were less likely to have therapeutic drug levels.

Serum MMP-3 Predicts a Subgroup with No Radiographic Progression in Rheumatoid Arthritis Patients with Low-Dose Methotrexate (MTX) M onotherapy. Kazuko Shiozawa\textsuperscript{1}, Takashi Yamasu\textsuperscript{1}, Miki Mura\textsuperscript{1}, T. Nakagawa\textsuperscript{2}, Norikai Yoko\textsuperscript{1}, Ryo Yokusuke\textsuperscript{1}, Yasushi Tanaka\textsuperscript{1}, Ken Tsumiyama\textsuperscript{2} and Shunichi Shiozawa\textsuperscript{1}.

1Kohnan Kakogawa Hospital, Kakogawa, Japan, 2Kyushu University Beppu Hospital, Beppu, Japan.

Background/ Purpose: Studies have shown that treating rheumatoid patients with methotrexate (MTX) monotherapy initially and later providing an option to step up to combination therapy produces outcomes similar to those seen with combination therapies of conventional drugs and/or biologics provided immediately (O’Dell \textit{et al.} Arthritis Rheum 65:1985, 2013). In their study, approximately 30% of patients treated with MTX monotherapy did not require subsequent combination therapy. However, this subgroup was clinically and radiographically indistinguishable from those who required it.

The purpose of the present study was to assess the efficacy of low-dose MTX monotherapy, a regimen which is commonly prescribed in Japan, and to identify a subgroup of patients whose radiographic progression is halted in response to MTX monotherapy. In the present study, 161 rheumatoid patients were treated continuously with low-dose MTX monotherapy continuously for 3 yrs until significant adverse events or radiographic progression were suspected.

Methods: Rheumatoid patients treated with low-dose MTX monotherapy (n=161) were followed prospectively for 3 yrs. Their disease activity and radiographic progression were evaluated with reference to disease activity score (DAS28), modified health assessment questionnaire (mHAQ) and others and by the change in van der Heijde-modified total Sharp score per year (fTSST), by classifying patients into subgroups showing structural remission (REM; fTSST<0.5), radiographic progression (fTSST>3) or rapid radiographic progression (RRP; fTSST>5).

Results: Disease activity was improved yearly, from baseline to 3 yrs: DAS28-ESR (3) improved from 3.2 ± 1.1 to 3.9 ± 1.4 (p < 0.0001), %DAS28 remission from 1% to 19%, mHAQ from 0.54 ± 0.47 to 0.18 ± 0.32 (p < 0.0001), mHAQ remission rate (fTSST<0.5) from 16% to 60%, and Boolean remission from 0.8% to 24.0%. During the 3-yr's MTX monotherapy, the ratio of the patients classified into the REM group increased from 38.5% to 50.4% (p = 0.0466), those in ΔTSS ≥ 3 decreased from 34.2% to 20.4% (p = 0.0095), and those in RRP decreased from 21.7% to 10.9% (p = 0.0190). In particular, the patients with active disease who required biologics arose mostly from the RRP group, followed by the CRRP group. This was, however, not the case when the patients were classified according to disease activity, i.e., DAS28. Receiver operating characteristic (ROC) curve analyses showed that serum matrix metalloproteinase-3 (MMP-3) levels of below 103.7 ng/ml at baseline predict a patient subgroup with no radiographic progression.

Conclusion: Approximately half of the patients given low-dose MTX monotherapy showed no radiographic progression over 3 yrs. A subgroup with no radiographic progression was predicted at outset by lower serum MMP-3.

Calprotectin Serum Levels Reflect Residual Inflammatory Activity in Patients with Rheumatoid Arthritis and Psoriatic Arthritis on Clinical Remission or Low Disease Activity Undergoing TNF-Antagonists Ther-apy. Jose Inclande-Mundo\textsuperscript{1}, M. Vicoria Hernandez\textsuperscript{2}, Sonia Cabrera-Villalba\textsuperscript{3}, Julio Ramirez\textsuperscript{4}, Andrea Cuervo\textsuperscript{1}, Virginia Ruiz-Esquide\textsuperscript{1}, A. Gonzalez Navarro\textsuperscript{1}, J. Ordag\textsuperscript{1}, Juan D. Cañete\textsuperscript{1} and Ramon Sanmarti\textsuperscript{1}.

1Hospital Clinic of Barcelona, Barcelona, Spain, 2Hospital Clinic Barcelona, Barcelona, Spain, 3Hospital Clinic Barcelona, Barcelona, Spain.
Background/Purpose: Calprotectin is a major S100 leucocyte protein, is associated to disease activity in rheumatoid arthritis (RA) and Psoriatic Arthritis (PsA) patients. Calprotectin is a potentially biomarker more sensitive of disease activity than conventional acute-phase proteins.

Objective: To analyze the relationship between calprotectin serum levels and inflammatory disease activity in patients with RA and PsA patients in clinical remission or low disease activity treated with TNF-antagonists. To correlate calprotectin levels with serum trough levels of TNF-antagonists.

Methods: Prospective study of patients diagnosed with RA (ACR 1987 criteria) or PsA (CASPAR criteria) treated with adalimumab (ADA), etanercept (ETN) or infliximab (IFX) for 3–12 months in clinical remission or with low disease activity measured by DAS28-ESR in ≥2 consecutive visits. Clinical and laboratory data were analyzed. Calprotectin serum levels (using kits from Promonitor®, Progenika SA) were determined at 0, 4, 8 and 12 months of follow-up. We present the results at study entry (visit 0).

Results: 103 patients (47 RA, 56 PsA) were included. 61% female, mean age 59 ±8 years, mean DAS28-ESR 2.1 ± 0.58, 76% were in clinical remission and 24% in low disease activity, 48% on monotherapy, 44% receiving reduced dosage of biologic (ADA 16 patients, ETN 22 patients and IFX 5 patients). Calprotectin levels were significantly lower in PsA than in RA patients (1.4 vs 2.2 ±1, p = 0.006). Patient on clinical remission (DAS28<2.6) showed lower calprotectin levels to those observed in those patients with low disease activity (1.2 ±1 vs. 3.4 ±1, p = 0.0001), even when distributed by the most stringent remission criteria (patients with SDAI 3.3 1.9 ±2, p = 0.005). Calprotectin strongly correlates with DAS28-ESR and SDAI in both RA (r = 0.774, p = 0.0001 and r = 0.328, p = 0.025 respectively) and PsA (r = 0.777, p = 0.0001 and r = 0.419, p = 0.001 respectively), whereas no correlation was found between CRP serum levels or ESR with DAS28-ESR and SDAI in both populations. A trend for higher calprotectin levels in patients with low serum trough levels of ADA was showed (n = 17, r = 0.413, p = 0.09), that was statistically significant in those patients with RA treated with adalimumab at standard dose (r = 0.767, p = 0.026). No correlations between calprotectin and serum trough levels ETN or IFX were observed.

Conclusion: Calprotectin was found to have high accuracy to discriminate RA or PsA patients in remission from those in low disease activity undergoing TNF-antagonist therapy, reflecting ongoing inflammatory activity. A strong correlation between disease activity measured by DAS28 and SDAI and calprotectin, but not with CRP or ESR, was found. No clear correlation between calprotectin levels and TNF-antagonists serum trough levels was observed. Calprotectin emerges as a very useful biomarker to detect residual inflammatory activity in these patients.

Baseline Serum Interferon Beta/Alpha Ratio Predicts Response to Tu

mer Necrosis Factor Alpha Inhibition in Rheumatoid Arthritis.

Priyanka Vashisth1, Jessica M. Dorschner2, Mark A. Jensen3, Beverly Chrabot3, Theresa Wampler M uskind2, Marlena Kernt3, Tetrad Investigators, ABCoN Consortium, 5, S. Louis Bridges Jr., P.K. Gregersen4 and Timothy B. Niewold1, 1University of Nebraska Medical Center, Omaha, NE, 2Mayo Clinic, Rochester, MN, 3University of Chicago, Chicago, IL, 4Feinstein Institute for Medical Research, Manhasset, NY, 5AL, 6NY, 7University of Alabama at Birmingham, Birmingham, AL, 8The Feinstein Institute for Medical Research, Manhasset, NY.

Background/Purpose: Response to tumor necrosis factor alpha (TNF-α) inhibition is variable in rheumatoid arthritis (RA). Previous studies have suggested that circulating type I interferon (IFN) levels may predict treatment response to TNF-α inhibitors and other biological agents in RA. Prediction of likely responders prior to initiating therapy would represent a major advance in biological treatment strategies for RA.

Methods: We used ELISA to quantify serum IL-33 level and assessed B-cell-activation biomarkers (rheumatoid factor [RF], anti-CCP antibodies, free light chains, IgG, IgA, IgM, and BAFF levels), serum CXCL12, CXCL13 and CCL19 levels (all log transformed for analysis) in 205 RA patients before receiving a 1st course of RTX (Ig on days 1 and 15) in the SMART trial and 63 controls (CT). Uni and multivariate analyses were performed to identify factors associated with a EULAR response 24 weeks after RTX.

Results: Serum IL-33 level was higher in patients with RA than in CT (median [interquartile range]: 238 [75;1545] vs 35 [22;664] pg/mL, p = 0.001) as well as in anti-CCP positive compared with anti-CCP negative patients (359 [87;1619] vs 102 [39;368] pg/mL, p = 0.001). A similar result was observed for RF status (p = 0.001). Serum IL-33 level was uncorrelated neither with DAS28 nor with CRP level. Unexpectedly, serum IL-33 level was highly correlated with CCL19 (r = 0.7; p = 0.0001) and CXCL13 levels (r = 0.15 p = 0.003). There were 146 (71%) responders (i.e. 44 good and 102 moderate) according to EULAR criteria at 12 weeks (p = 0.02), as well as the presence of anti-CCP antibodies or RF (OR: 2.76 [1.24;6.15]; p = 0.01), with a similar trend for IgG level (OR: 2.00...
IFN activity were evident, these patients were indistinguishable in regards to key SS phenotypic features, except focus score which was highest in type II-predominant patients (p = 0.024). Stratification of SS patients by high vs low IFN activity revealed associations of high IFN activity with high titer ANA (p = 0.0016) and SSA (p = 0.0161) antibodies, hyperglobulinemia (IgG >1445 mg/dl, p = 0.0005; IgA >400 mg/dl, p = 0.0355) and higher focus scores (p = 0.0001). Additionally IFN high patients demonstrated greater evidence of glandular dysfunction as determined by decreased ability to produce saliva (UWS: 0.164 vs 0.549 ml/5min, p = 0.0003) and tears (Schirmer 4 vs 6.5 mm/5min, p = 0.0368).

Conclusion: Our data indicate that the parent phenotype in SS (chronic exocrine gland dysfunction, inflammatory infiltration and autoimmunity) includes distinct molecular subtypes, segregated by magnitude and pattern of IFN responses. While the resulting disease subtypes are clinically similar, therapies targeting type I and type II IFN may need to be selected based on prior analyses of which specific IFN pathway(ies) are active in individual patients.

Precisely Quantified Fibrosis in Labial Salivary Glands Predicts Sjogren’s Syndrome Classification in a Multiple Regression Model.

Kerry M. Leehan1, Michael Brown2, Courtney Montgomery2, A. Strid Rasmussen2, David M. Lewis1, Lida Radfar1, Donald U. Stone1, Stephen Young1, R. Hal Scofield1, Kathy L. Moser Sivils2 and A. Darise Farris2.

1University of Oklahoma Health Sciences Center, Oklahoma City, OK, 2Oklahoma Medical Research Foundation, Oklahoma City, OK.

Background/Purpose: Primary Sjögren’s Syndrome (pSS) is a systemic, progressive autoimmune exocrinopathy that presents diagnostic challenges. Focal lymphocytic infiltrates in labial salivary gland (SG) biopsies, serum autoantibodies, objective measures of dryness, and patient-reported symptoms are used to classify pSS. Because focus score (FS) may vary with course of disease, we asked whether precisely quantified SG fibrosis can distinguish pSS from non-SG sicca.

Methods: Formalin-fixed biopsy sections (4-6 glandular cross-sections per subject) collected from symptomatically dry individuals attending the Oklahoma Sjögren’s Syndrome Center of Research Translation clinic were stained with hematoxylin/eosin, imaged and digitally reconstructed. A metric European Consensus Group (AECG) classification status (n=50 pSS; n=28 non-SS) was blinded in order to eliminate bias by the scorers. AECG pSS exclusions were applied to all subjects. Fibrosis was quantified using a digital grid overlay; sections were scored and reported as average percent area

Results: Fibrosis was significantly increased (p=0.0004, Mann-Whitney U) in pSS salivary glands (median 25.39%, range 1.788%-70.45%) compared to non SS sicca subjects (median 15.52%, range 8.876%-31.38%). Among pSS subjects, fibrosis correlated with age (p=0.029, r=0.307), lip biopsy focus score (p=0.03, r=0.360) and van Bijsterveld Score (vBS, p=0.02, r=0.310). No significant correlation between fibrosis and salivary flow or Schirmer’s score was observed. In a predictive model including fibrosis and age, degree of labial salivary gland fibrosis predicted disease classification with 68% accuracy irrespective of age of fibrosis (p=3.91x10⁻³; age, p=0.63).

Conclusion: Although age is associated with salivary gland fibrosis, multiple regression analysis suggests that labial salivary gland fibrosis is a significant feature of primary Sjögren’s syndrome regardless of age.

Molecular Diagnostics for Patient Subsetting in Sjögren’s Syndrome.

John C. Hall1, Alan N. Baer1, M. Y. Lam2, Lindsey A. Criswell3, Antony Rosen4 and Livia Casciola Rosen5. 1Johns Hopkins University School of Medicine, Baltimore, MD, 2University of California San Francisco, San Francisco, CA, 3University of California, San Francisco, Rosalind Russell/ Epiphram P. Englman Rheumatology Research Center, San Francisco, CA.

Background/Purpose: Sjögren’s syndrome (SS) is a chronic autoimmune disease which targets exocrine glands, particularly salivary and lacrimal glands. While all SS patients have abnormal secretory function and inflammatory infiltration of their salivary glands, there is significant heterogeneity in terms of disease features, pathology and clinical course. Elucidating the inflammatory pathways which are active in pathologic tissues has important implications for defining disease subsets and monitoring disease activity. With the increasing availability of therapies which target specific gene/enzyme in the inflammatory pathways which are active in pathologic tissues has important implications for defining disease subsets and monitoring disease activity. With the increasing availability of therapies which target specific gene/enzyme pathways, defining the activity of distinct molecular pathways in target tissues will be important for selecting therapy. The type I and type II IFNs, which are implicated in SS pathogenesis, are particularly relevant in this regard.

Methods: Clinical data and a frozen labial salivary gland was obtained from each of 82 participants enrolled in the Sjögren’s International Collaborative Alliance Registry (NIH/NIDCR contract HHSN265201300057C) with the following characteristics: (i) 53 individuals meeting ACR criteria for primary SS; (ii) 26 age and sex-matched controls lacking serologic and pathologic evidence of SS, of which 14 exhibited evidence of dry eye disease (OSS = 3 for either eye). Protein lysates were generated from SS and control labial salivary glands proteins were separated by SDS-PAGE and immunoblotted with specific markers of type I or type II IFN activity. Protein expression was normalized to the level of a loading control within the same sample and subject to hierarchical clustering to define patterns of IFN activity (high vs low). Correlations between IFN activity and categorical SS phenotypic features were analyzed using Fisher’s exact test. Continuous phenotypic characteristics were compared between groups using a Wilcoxon rank sum test.

Results: IFN activity was low or absent in controls and detected at high levels in 31 of 53 (59%) SS patients. While patterns consistent with type I-predominant (n=9), type II-predominant (n=11) and mixed I/II (n=11)
Background/Purpose: Recently, convincing data have been published on the diagnostic value of salivary gland ultrasonography (SGUS) in primary Sjögren’s syndrome (pSS). However, a limited number of information are available on the contribution of SGUS in the patients’ prognostic assessment and in the monitoring of the response to therapy during the follow-up. A aim of the study was to prospectively evaluate if SGUS might have a role in the prognostic stratification and in the monitoring of the disease activity in patients with pSS over the follow-up.

Methods: The study population consisted of consecutive patients with a diagnosis of pSS (AECG 2002) who prospectively underwent clinical laboratory and SGUS assessment at baseline, at 12 and at 24 months. An experienced rheumatologist scored the EULAR Sjögren’s Syndrome Activity Index (ESSDAI) at each follow-up time point. Patients received the “best available-therapy” according to the clinical practice. SGUS was performed by the same radiologist blinded to the rheumatologist clinical assessment. The parotid and submandibular glands were scanned on both sides by using a real-time US scanner (Esaote Technos MPX) with a 7.5–12.5 MHz transducer and the following US parameters were recorded: size, parenchymal echogenicity and inhomogeneity in the parotid and submandibular glands on both sides. A previously reported ultrasound scoring system (De Vita 1992) was used to grade the echostructure alterations of the salivary glands. Baseline, 12 months and 24 months SGUS results were compared using the non-parametric Friedman test for multiple comparisons. Correlation between SGUS and ESSDAI changes throughout the follow-up period was assessed using the Spearman linear correlation coefficient. Statistical significance was accepted at p<0.05.

Results: From January 2012 and January 2014, 68 pSS patients were enrolled in this study (median (IQR) age: 53 (45–64) years). At the baseline 28/68 (41.2%) patients had a SGUS score ≥2. These patients, when compared to the group of patients with a SGUS score <2, presented more frequently low C4 levels (p=0.04), positivity for anti-Ro/SSA (p=0.0001) and higher mean ESSDAI scores, with the ESSDAI positively correlating with the SGUS score (r=0.571, p<0.0001). Over the follow-up we still observed a positive correlation between the changes in the ESSDAI and the changes in the SGUS score (r=-0.490, p=0.0001). However, no statistically significant differences were detected over the follow-up in the SGUS score across the multiple test performed and at the end of the study patients with grossly inhomogeneous glands still presented evident inhomogeneities.

Conclusion: This study highlighted the positive correlation between SGUS score and pSS disease activity. However, further research is needed before a conclusion can be made regarding the possibility of using SGUS in the assessment of the response to therapy in pSS.

Marko Yurkovich1, Hyon K Choi2, Eric C. Sayre3, Kamran Shojania1 and J. Antonio Pereira1, Cleonice Bueno 1, Vilma S. T. Viana 3 and Sandra G. Pasoto 1.

Background/Purpose: Recently, convincing data have been published on the diagnostic value of salivary gland ultrasonography (SGUS) in primary Sjögren’s syndrome (pSS). We estimated the population-based risk of newly recorded DVT and PE among incident cases with pSS compared to controls from the general population using physician-billing and hospitalization databases that cover the entire population of the province of British Columbia, Canada (~4.4 million).

Patients and Methods: Our data include all visits to health professionals and all hospital admissions from Jan 1, 1995 to Dec 31, 2010 for all individuals. We conducted a retrospective matched cohort study among patients satisfying at least one of the following criteria: a) diagnosis of pSS in adults on at least two visits within a two-year period between Jan 1996 and Dec 2010 by a non-rheumatologist physician; b) diagnosis of pSS on at least one visit by a rheumatologist or from hospitalization. To increase specificity we excluded cases that were not confirmed by a rheumatologist if they were seen at a later point. pSS cases that were matched by birth year, sex and calendar year of follow-up were selected from the general population for each outcome. Cases involved PE, DVT, and PE or DVT events based on hospitalization records (for PE and DVT), outpatient visits (DVT) or death certificates (all outcomes). For non-fatal outcomes, we also required the use of anticoagulant medication within six-months of the event as part of all outcome definitions. We estimated relative risks (RRs) comparing pSS with age-, sex- and entry-time-matched comparison cohorts, adjusting for potential risk factors for PE and DVT. Sensitivity analyses were conducted to assess for unmeasured confounders.

Results: Among 1175 incident SjS cases, 14, 10 and 19 developed a first time PE, DVT, and PE or DVT event, respectively (incidence rates = 3.8, 2.7 and 5.2 per 1,000 person years, respectively) (see table). Compared with the age, sex, and entry-time-matched controls, the RR were 4.1 (95% CI: 2.0 – 7.7), 3.0 (95% CI: 1.3 – 6.1) and 3.1 (95% CI: 1.8 – 5.3) for PE, DVT, and DVT or PE, respectively. After adjusting for covariates the results remained similar (see table). The risk of developing DVT, PE or either event was highest within the first year following diagnosis of SjS, decreasing over time to become not significantly increased after 5 years. Our results remained statistically significant after adjusting for the potential impact of an unmeasured confounder (adjusted RR ranging between 1.58 – 1.98 in all sensitivity analyses).

Conclusion: This large population-based study indicates an increased risk of DVT and PE in patients with SjS. Our results support the need for increased monitoring for these complications in SjS patients.

| Table: Risk of Incident PE, DVT or PE or DVT according to SjS Status |
|-----------------|-----------------|-----------------|-----------------|-----------------|
|                  | PE              | DVT             | PE or DVT       |
| Sample size, n   | 1,175           | 11,958          | 1,175           | 11,958          |
| RRs (95% CI)     |                 |                 |                 |
| Time After Initial Diagnosis: |                 |                 |                 |
| < 1 year         | 8.9 (2.7 – 28.0) | 5.0 (1.4 – 16.3) | 5.7 (2.3 – 12.9) |
| < 2 years        | 6.2 (2.4 – 15.0) | 5.1 (1.8 – 13.6) | 4.6 (2.1 – 9.4) |
| < 3 years        | 4.7 (2.0 – 10.4) | 4.4 (1.7 – 10.5) | 4.0 (2.0 – 7.5) |
| < 4 years        | 5.0 (2.3 – 10.5) | 4.3 (1.8 – 9.8)  | 4.0 (2.0 – 7.1) |
| < 5 years        | 4.8 (2.2 – 9.7)  | 4.0 (1.6 – 9.0)  | 3.7 (1.9 – 6.6) |
| ≥ 5 years        | 2.3 (1.0 – 5.6)  | 1.0 (0.0 – 6.5)  | 1.9 (0.4 – 6.5) |
| Multivariate RRs*| 3.2 (1.6 – 6.5)  | 2.8 (1.2 – 6.4)  | 2.4 (1.3 – 4.4) |

Metabolic Syndrome, Adipocytokines and Inflammation in Sjögren’s Syndrome.

Faculty of Medicine of the University of São Paulo, São Paulo, Brazil, 2University of São Paulo, São Paulo, Brazil, 3Faculty of Medicine of the University of São Paulo, São Paulo, Brazil.

Background/Purpose: Systemic inflammation has been linked to increased frequency of metabolic syndrome (MetS) in autoimmune diseases. However, there are no studies concerning the frequency of this complication and adipocytokine sera profile in Primary Sjögren’s syndrome (SS).

Methods: Seventy-one female SS patients (American-European Consensus Group Criteria), aged 18–65 years and 71 healthy women matched for age and race were enrolled in this case-control study. Clinical data were collected by a standardized questionnaire and physical examination at inclusion. Serum levels of glucose, total cholesterol, low density lipoprotein (LDL), high density lipoprotein (HDL), triglycerides, interleukin-1 beta (IL-1b), IL-6, BAFF, insulin, leptin, adiponectin, visfatin, resistin, ghrelin and plasminogen activator inhibitor-1 (PAI-1) were determined for all patients and controls. MetS (International Diabetes Federation) and disease activity (EULAR Sjögren’s Syndrome Disease Activity Index (ESSDAI)) were also determined.

Results: Patients and controls were comparable regarding mean age (47.6 ± 10.3 years vs. 47.2 ± 10.3 years, p=0.833), ethnicity (white: 77.5 vs. 77.5 %, p=1.00), body mass index (BMI) (27.6 ± 6.4 vs. 26.7 ± 3.6 kg/m², p=0.783), smoking (p=0.538), sedentary lifestyle (p=0.847) and menopause...
Background/Purpose: In an open-label proof of concept study, Abatacept is under investigation.

Methods: Fifteen patients with pSS, diagnosed according to the revised American-European Consensus Group criteria, were treated with Abatacept on days 1, 15, 29 and every four weeks thereafter for five months (~10 mg/kg of body weight i.v.). Absolute numbers and frequencies of circulating Th-cell subsets (CD3+CD4+) were examined in fresh blood samples by flow cytometry at baseline and week 1, 2, 4, 12, 16, 24, 36 and 48 weeks after the first dose. Expression patterns of chemokine receptors CCR7 and CD45RO were used for distinction between naive, central memory, effector memory and terminally differentiated Th-cells. Generalized estimating equations (GEE) were used to analyze the presence of different subsets over time in subjects, as well as their association with arthritis activity (ESSDAI). For distinction between naive, central memory, effector memory and terminal differentiated Th-cells, GEE analysis with adjustment for age, ethnicity, current and cumulative prednisone doses and usage time revealed that MTS group had higher values of hypertension (p < 0.001), HOMA-IR (p < 0.001), LDL (p < 0.014), VLDL (p < 0.001), triglycerides (p < 0.001), glucose (p < 0.014), lipoprotein (p < 0.006), leptin (p < 0.008) and IL-1β (p < 0.008).

Conclusion: This study identified a high frequency of MTS and an abnormal adipocytokine profile in pSS patients. The interesting association of MTS with elevated IL-1β suggests that inflammation plays an important role in its pathogenesis in SS.

Abatacept reduces Circulating Efferent Memory T-Helper Cells in Patients with Primary Sjögren’s Syndrome (pSS).

Gwenn Verstappen1, Wjeyl H. Abdulahad2, Petra M. Meiners1, Suzanne Arends1, Silvia Beijer-Liefers1, Arian J Visink1, Frans G. M. Kroese2 and Hendrika Bootma2.

1University Medical Center Groningen, University of Groningen, Groningen, Netherlands; 2University Medical Center Groningen, Groningen, Netherlands.

Background/Purpose: In an open-label proof of concept study, Abatacept is a fully human fusion molecule of IgG-Fc and CTLA-4 that modulates the costimulatory interaction between APCs and T-lymphocytes, thereby inhibiting full T-cell activation. Modifying T-helper (Th) cell homeostasis may contribute to the therapeutic effect of Abatacept as Th-cell subset imbalances are involved in the emergence of autoimmunity and arthritis.

Methods: Fifteen patients with pSS, diagnosed according to the revised American-European Consensus Group criteria, were treated with Abatacept on days 1, 15, 29 and every four weeks thereafter for five months (~10 mg/kg of body weight i.v.). Absolute numbers and frequencies of circulating Th-cell subsets (CD3+CD4+) were examined in fresh blood samples by flow cytometry at baseline and week 1, 2, 4, 12, 16, 24, 36 and 48 weeks after the first dose. Expression patterns of chemokine receptors CCR7 and CD45RO were used for distinction between naive, central memory, effector memory and terminally differentiated Th-cells. Generalized estimating equations (GEE) were used to analyze the presence of different subsets over time in subjects, as well as their association with arthritis activity (ESSDAI).

Results: On Abatacept treatment, numbers of peripheral blood CD4+ T-cells did not significantly differ from baseline values. However, absolute numbers and frequencies of total memory Th-cells decreased significantly over time on treatment (p = 0.001 and p = 0.001, resp.). This was mainly a result of a decrease in effector memory Th-cells. On treatment, both absolute numbers and frequencies of effector memory Th-cells decreased significantly over time (p = 0.011 and p = 0.001, resp.), with the largest decrease seen at week 24. On the contrary, frequencies of naive Th-cells increased over time on treatment (p < 0.001). From week 24 to week 48 (off treatment), a trend towards increased absolute numbers and frequencies of effector memory Th-cells was observed. Decrease and repopulation of Th-cell subset correspond to changes in disease activity as assessed with ESSDAI.

Conclusion: CTLA-4Ig treatment with Abatacept decreases the presence of circulating effector memory Th-cells of pSS patients. The observation that decrease and repopulation of effector memory Th-cells correspond to changes in disease activity suggests that these cells are -at least partially- responsible for the effects of Abatacept treatment seen in pSS patients.

Attainment of Minimal Disease Activity Using Methotrexate in Psoriatic Arthritis.

Barry J. Sheane, Arane Thavaneswaran, Dafna D. Gladman and Vinod Chandran. University of Toronto, Toronto Western Hospital, Toronto, ON.

Background/Purpose: Methotrexate (MTX) is used as first-line treatment in psoriatic arthritis (PsA); however, the extent of the disease-modifying effect of MTX on PsA, if any, is not established. Randomized controlled trials examining the efficacy of MTX have been either under-powered or have used dosages that may be sub-optimal. While TNF inhibitors (TNF-I) are used as second-line therapies in PsA, they have proven efficacy and disease-modifying effect. Minimal disease activity (MDA) is achieved at 24 weeks in 39% and 52% of patients treated with adalimumab and infliximab, respectively. There is a need to establish the treatment effect of MTX.

Methods: All patients attending a large, tertiary referral centre for PsA who initiated MTX and were naive to biologic medication on or after January 2004 up until April 2014 were assessed for inclusion. The primary outcome was the achievement of MDA after 6 months of MTX. MDA is defined as: the presence of at least 5 out of the following 7 domains: tender joint count ≤ 1, swollen joint count ≤ 1, Spondylarthritis Assessment Questionnaire score ≤ 0.5, patient global assessment of disease activity Visual Analogue Scale (VAS) score ≤ 20 and patient pain VAS ≤ 15.

Results: Of 204 patients identified, 29 had insufficient duration on MTX to accurately assess outcome. These were excluded, leaving 175 for analysis. Of these, 167 patients had sufficient data for analysis at 6 months.

Conclusion: These findings suggest that MTX is efficacious in the treatment of PsA and should be further evaluated in future studies.

Is AnaKlyosing Spondylitis a Risk Factor for Cardiovascular Diseases, and How Does This Risk Compare to Those in Rheumatoid Arthritis?

Johan Aaskling1, Lennart Jacobsson2 and Jonas Eriksson3.

1Clinical Epidemiology Unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden; 2 Sahlienska academy, Gothenburg, Sweden.
Performance of the models was evaluated (sensitivity, specificity, positive predictive value, positive likelihood ratio) using classification by ASAS axSpA criteria as external standard. For pts not fulfilling the ASAS criteria who are referred, post-test probability for axSpA was calculated based on the LR product for presence of SpA features. A LR product $\geq 78$ equals a post-test probability $\geq 80\%$ and was used as cut-off for probable axSpA. Pts who were incorrectly not referred met the ASAS axSpA criteria by fulfilling the clinical arm only or the imaging arm (imaging arm only or both arms). [table 2]

Table 2. Performance of referral models. Sens, sensitivity; Spec, specificity; PPV, positive predictive value; LR+, positive likelihood ratio; PTP, post-test probability

Results: In total, 74/192 pts fulfilled ASAS axSpA criteria; 48 with positive imaging (n=15 radiographic sacroiliitis). Most models performed well regarding sensitivity/specificity. Braun alt. model has the most balanced sensitivity/specificity and highest LR+. All models that include HLA-B27 miss axSpA pts with positive imaging, 14–23% with radiographic sacroiliitis (depending on the model). PPV of the models is low, indicating that many pts are referred despite not fulfilling ASAS axSpA criteria. However, 6–16% (depending on the model) of these pts have a post-test probability $\geq 80\%$ for axSpA. This reflects that these pts are rightly referred, despite not fulfilling the axSpA criteria.

Conclusion: Most referral models performed well in the SPACE cohort. However, this cohort includes pts already referred from primary care, probably causing overestimation of performance of all models. All models miss pts fulfilling the ASAS imaging arm, 14–23% of which have radiographic sacroiliitis, which is highly undesirable. Moreover, large numbers of pts referred unnecessarily might lead to a burden for health care systems. Further studies should be conducted in primary care to evaluate these models in their target population.

Evaluation of Referral Models for Axial Spondyloarthritis in Primary Care in the Spondyloarthritis Caught Early Cohort. Ozair Abawi, Rosaline van den Berg, Désirée van der Heijde and Floris van Gaalen, Leiden University Medical Center, Leiden, Netherlands.

Background/Purpose: Several models have been proposed to refer patients (pts) with possible axial spondyloarthritis (axSpA) from primary care to the rheumatologist. Aims of the study was to evaluate performance of referral models for axSpA in the SPondsYoArthitis Caught Early (SPACE) cohort.

Methods: Ten referral models were found in literature and tested in the Leiden SPACE cohort, including pts with back pain ($\geq 3$ months, $\geq 2$ years, onset $< 45$ years; n=192) referred to the rheumatology outpatient clinic of the LUMC. Imaging was omitted from all models if included as a referral parameter, as it is useless for screening in primary care. [table 1]

Table 1. Characteristics of referral models. IBP, inflammatory back pain; IBD, inflammatory bowel disease

Results: Total, 74/192 pts fulfilled ASAS axSpA criteria; 48 with positive imaging (n=15 radiographic sacroiliitis). Most models performed well regarding sensitivity/specificity. Braun alt. model has the most balanced sensitivity/specificity and highest LR+. All models that include HLA-B27 miss axSpA pts with positive imaging, 14–23% with radiographic sacroiliitis (depending on the model). PPV of the models is low, indicating that many pts are referred despite not fulfilling ASAS axSpA criteria. However, 6–16% (depending on the model) of these pts have a post-test probability $\geq 80\%$ for axSpA. This reflects that these pts are rightly referred, despite not fulfilling the axSpA criteria.

Conclusion: Most referral models performed well in the SPACE cohort. However, this cohort includes pts already referred from primary care, probably causing overestimation of performance of all models. All models miss pts fulfilling the ASAS imaging arm, 14–23% of which have radiographic sacroiliitis, which is highly undesirable. Moreover, large numbers of pts referred unnecessarily might lead to a burden for health care systems. Tuesday, November 18
Background/Purpose: Axial spondyloarthritis (axSpA), including ankylosing spondylitis and nonradiographic axial SpA (nr-axSpA), is an chronic inflammatory disease marked by back pain and progressive spinal stiffness. The goal of GO-AHEAD was to determine if golimumab (GLM) is superior to placebo (PBO) in patients with nr-axSpA.

Methods: GO-AHEAD was a Phase 3b, double-blind, randomized, PBO-controlled trial that evaluated subcutaneous (SC) GLM 50 mg vs PBO in patients aged 18–45 years with active nr-axSpA (A assessment of Spondyloarthritis International Society (ASAS) criteria and centrally-read SI joint X-rays; disease duration <5 years; chronic back pain; high disease activity [total back pain ≥40 mm on a 0–100 mm VAS] and Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) ≥4 mm); and inadequate response or intolerance to NSAIDs). Patients were randomized 1:1 to GLM or PBO SC injections every 4 weeks. The primary endpoint was BASDAI 20 attainment at week 16. Key secondary endpoints were ASAS 40, ASAS partial remission, and BASDAI 50 attainment; and Spondyloarthritis Research Consortium of Canada (SPARCC) magnetic resonance imaging (MRI) sacroiliac (SI) joint score change. AS Disease Activity Score based on C-reactive protein (ASDAS) was assessed. Treatment group differences for all patients-as-treated and the target populations (signs of inflammation by MRI or elevated CRP at baseline) were compared using the stratified Miettinen and Nurminen method for responder endpoints and the Mann-Whitney test for MRI SI joint score.

Results: Of 198 patients enrolled, 197 were treated (GLM=97; PBO=100). Mean age was 31 years; 57% were male. At baseline, mean BASDAI was 6.5 cm (SD=1.5), SPARCC MRI SI was 11.3 (SD=14.0), and ASDAS was 3.5 (SD=0.9). The primary endpoint was achieved by significantly more GLM patients than PBO patients (40.0%; table). Significantly more GLM patients also attained ASAS 40, ASAS partial remission, and BASDAI 50 (table). Mean ASDAS improvements were greater with GLM than PBO (−1.7 vs −0.6, respectively; P<0.0001). Mean SPARCC MRI SI joint score improvements from baseline to week 16 were greater with GLM than PBO (−5.3 vs −0.9, respectively; P<0.0001; improvements for the target population were −6.4 vs −1.2, respectively (P<0.0001).

Conclusion: More GLM patients than PBO patients met the primary endpoint of BASDAI 20 attainment; and GLM also met key ASAS 40, BASDAI 50, and SPARCC MRI SI joint score secondary endpoints. GLM improved disease activity and MRI SI joint scores in patients with nr-axSpA.

* Differences derived from the statistical model.

Adverse events (AEs) occurred in 41% of GLM and 47% of PBO patients. Serious AEs occurred in 1 GLM (female partner reported fetal death) and 2 PBO patients (cholelithiasis, back pain). There were no serious infections, serious opportunistic infections, active tuberculosis, malignancies, serious drug-induced hepatotoxicity, or deaths, but without classic X-ray changes of AS. The second was the introduction of a new entity called non-radiographic axial Spondyloarthritides (nr-axSpA), defined based on the presence of MRI changes and HLA-B27, but without classic X-ray changes of AS. We studied the changes in incidence and prevalence of spondyloarthropathies (SpA) over time in Ontario, Canada.

Methods: We performed a population-based, retrospective cohort study on patients with SpA, age 15 or above, living in Ontario between 1995 and 2010. We used a stringent SpA definition of 2 outpatient claims within 2 years with at least one inpatient or rheumatologist claim. Incidence rates, prevalence rates and confidence intervals were calculated using Poisson regression. The incidence of SpA in men and women were compared in the pre-biologic era (1995–2000), early biologic era (2000–2005) and late biologic era (2005–2010).

Results: A total of 21,878 SpA patients were identified. The age, sex and local health integration network (LHIN) standardized prevalence rates (per 100,000) for SpA were 79 in 1995, 132 in year 2000, 175 in 2005 and 213 in 2010. The male:female ratio dropped from 1.25 to 1.08 to 1.03 in 2005–2010. The incidence rates rose uniformly in all age groups (15–44 years, 45–64 years and above 65 years) with time.

Conclusion: In this large population-based study, the period specific adjusted prevalence of SpA progressively increased. More female patients were diagnosed with SpA from 2000 onwards which correlates with the introduction of TNFi therapy in AS. Thus the trend of increasing female SpA patients predate the introduction of MRI and the new ASAS classification criteria for axial SpA.

Physical Function Is Independently Associated with Mortality Among Individuals with Knee and/or Hip OA: The Johnston County Osteoarthrits Project. Rebecca Cleveland, Todd Schwartz, Jordan B. Renner, Joanne M. Jordan and Leigh F. Callahan.

**Background/Purpose:** Declining physical function (PF) is a common consequence of osteoarthritis (OA), and poor PF is associated with death. It is possible that the resulting reduction in physical activity may increase an individual’s risk of development or progression of life-threatening chronic diseases such as CVD and diabetes; however, we previously found that individual knee and/or hip OA was independent of comorbidities. We therefore sought to examine whether poorer PF among those with OA was associated with death at subsequent follow-up, independent of comorbidities associated with reduced PF.

**Methods:** Data were from 1,525 individuals aged 45 or older with radiographically confirmed (KL grade ≥2) knee and/or hip OA (ROA) who entered the cohort during the original study enrollment (1990–1997) and newly enrolled individuals recruited during the cohort enrichment (2003–2004). Vital status was assessed at first follow-up period (1999–2004 for original participants; 2007–2010 for new enrols). Severe ROA was defined as a KL grade ≥3; symptomatic OA (sOA) was a subset of those with ROA and symptoms in the same joint. PF assessment was the 8-ft (2.4-m) walk test. A average number of steps needed to complete the walk and average times to the nearest tenth of a second across two trials were computed. Dichotomous variables based on medians were used for walk time (<3.4 sec and ≥3.4 sec) and number of steps (<5.5 steps and ≥5.5 steps). Multilevel logistic regression models controlling for the primary sampling unit (PSU) were used to estimate odds ratios (OR) and 95% confidence intervals (CI) for the associations between each PF measure at baseline and whether death occurred by the first follow-up evaluation. All models were adjusted for age, race, sex, BMI, smoking, depression, stroke, diabetes and CVD.

**Results:** Our sample was mostly women (63%), Caucasian (67%) and had a mean age of 65 years. At first follow-up, 18% of our sample had died. Walking time and number of steps above their medians were associated with a doubling in the odds of death among those with knee and/or hip ROA (Table 1). Similar associations were observed when restricted to individuals with sOA, and slightly attenuated ORs among those with severe disease that failed to reach statistical significance, possibly due to a smaller sample size. The highest odds of death with greater walking times were seen among individuals who had knee ROA whether with knee ROA (OR = 2.33; 95% CI = 1.20–4.51) or without knee ROA (OR = 2.40; 95% CI = 1.25–4.61).

**Conclusion:** Our findings suggest that poor PF among a cohort of individuals with knee and/or ROA is associated with death, findings which are independent of comorbidities linked to increased mortality. We observed associations with death were particularly strong for individuals with hip ROA, therefore suggesting a potential survival benefit through intervention among those individuals.

Table 1. A adjusted odds ratios (95% CI) for death at first follow-up according to 8-foot walking test measures assessed at baseline among those with knee and/or hip ROA (n = 1,525).

**References:**

BG (18.5–24.9) and current smokers vs non-smokers (OR: 1.62; 95% CI: 1.42 – 1.88). Physical activity was not significantly associated with arthritis. Further analysis showed that the population-level effects of increasing education and income on reducing the arthritis prevalence were almost count-balanced by effects of increasing BMI (obesity).

Conclusion: The findings suggest that the cohort effect of more arthritis in younger cohorts is explained by period effects such that the potential benefits of increased education and income in reducing the prevalence of arthritis may have been partly offset by increases in BMI over time. Our understanding of the impact of BMI on arthritis is therefore likely to be an underestimate. The cohort effect of increased arthritis in younger cohorts also suggests that previous population projections may be underestimated.

Severity of Foot Pain Is Linked to the Prevalence of Depressive Symptoms: The Framingham Foot Study.

Background/Purpose: The Framingham Foot Study. Severity of foot pain with depressive symptoms in a population-based study was studied. The purpose of this study was to examine the associations of foot pain (yes or no) and severity of foot pain with depressive symptoms in older adults.

Methods: A validated foot assessment and the 20-item CES-D questionnaire were administered to Framingham Foot Study (2002–08) participants. Age, sex, race/ethnicity, education and income on reducing the arthritis prevalence were almost significantly associated with 44% decreased risk of disability (HR = 0.56 [95% CI, 0.37–0.81], P = 0.003). From further analyses using an isotemporal model, replacing one hour sedentary time with one hour light activity (e.g. walking) was associated with 53% decrease in risk of disability onset for those in the most sedentary quartile, independent of potential confounders and time spent in other activities (HR = 0.49 [95% CI, 0.29–0.85], P = 0.01; not shown in Figure).

Conclusion: Sedentary time appears to be a separate and distinct risk factor for incident disability among adults at elevated risk for disability. In addition to increasing MVPA physical activity, these findings suggest decreasing sedentary time may be an additional strategy to prevent disability onset.

Sedentary Time Is an Independent Risk Factor for Disability Onset Among Adults at Elevated Risk: Prospective Cohort Study.

Jungwha Lee, Jing Song, Barbara Airdworth, Rowland W. Chang, Linda S. Ehrlich-Jones, Christine Pfeiffer, Dr. Pamela Silverman and Dr. Sushama Vohra. Northwestern University Feinberg School of Medicine, Chicago, IL, 2Arizona State University, Phoenix, AZ, 3Rehabilitation Institute of Chicago, Chicago, IL, 4Rush University, Chicago, IL, 5Northwestern University, Chicago, IL.

Background/Purpose: Disability threatens personal independence and is a major driver of health care costs. Physical activity has been shown to prevent disability. Sedentary behavior, already associated with poor health outcomes, may have a unique relationship to the development of disability or simply reflect limited recommended moderate/vigorous physical activity (MVPA). If a separate and distinct risk factor, reducing sedentary behavior may provide an additional strategy to reduce disability among older adults.

Methods: Prospective multi-site cohort of 1680 community dwelling adults aged 49 years or older were at elevated risk to develop disability due to knee osteoarthritis or having knee osteoarthritis risk factors. Baseline sedentary and non-sedentary (e.g., light, moderate, vigorous) time were objectively measured using accelerometers. Participants were classified into sedentary time quartiles. Disability was ascertained from limitations in instrumental and basic activity of daily living (IADL/AADL) at baseline and two years. Hazard ratios for disability onset over 2 years follow-up were estimated from discrete time proportional hazards models controlling MVPA time, socioeconomic factors (age, sex, race/ethnicity, education, income), health factors (function, comorbidity, Center for Epidemiological Studies Depression score, body mass index category, current smoking, knee pain, knee OA severity, knee symptoms, knee injury, other lower extremity joint pain, gait speed).

Results: Incident disability was 147 versus 69, 62, and 72 per 1000 person-years over 2-years follow-up in the most sedentary quartile (>=11.5 sedentary hours per day) compared to the three less sedentary quartiles, respectively. Less sedentary time was significantly associated with decreased risk of disability independent of moderate/vigorous minutes and other covariates (hazard ratios comparing three less sedentary quartiles vs. the most sedentary quartile, 0.62, 0.52, 0.57, respectively) (Figure). The average of the three less sedentary quartiles compared to the most sedentary quartile was associated with 44% decreased risk of disability (HR = 0.56 [95% CI, 0.37–0.81], P = 0.003). From further analyses using an isotemporal model, replacing one hour sedentary time with one hour light activity (e.g. walking) was associated with 53% decrease in risk of disability onset for those in the most sedentary quartile, independent of potential confounders and time spent in other activities (HR = 0.49 [95% CI, 0.29–0.85], P = 0.01; not shown in Figure).

Conclusion: Sedentary time appears to be a separate and distinct risk factor for incident disability among adults at elevated risk for disability. In addition to increasing MVPA physical activity, these findings suggest decreasing sedentary time may be an additional strategy to prevent disability onset.

Background/ Purpose: Foot pain is associated with poorer physical function in older adults, but few studies have examined how foot structure (high / low arches) and foot function (supination / pronation) are related to lower extremity physical function. The purpose of this cross-sectional study was to evaluate whether foot structure and function were associated with self-report and performance-based physical function in a community-based study of Caucasian and African American men and women 50+ years old.

Methods: During the 2006-2010 exam of the Johnston County Osteoarthritis Project, foot pressure scans were obtained and physical function of participants was assessed via self-report and performance tests. Physical function measures included: the Foot and Ankle Outcome Score – A-activities of Daily Living subscale (FAOS-ADL, 0-100 [extreme - no limitation]), 5 timed chair stands (unable and quartiles of completion time in seconds [s]), 8-foot walk (unable and quartiles of time in s), and standing balance (unable to stand without assistance, <10 s semi-tandem, semi-tandem 10 s but unable full tandem >2 s, full tandem 3-9 s, and full tandem 10 s). Foot pressure scans were used to determine foot structure (modified arch index) during standing and foot function (center of pressure excursion index) while walking. Based on population data, foot structure was categorized as high arch, low arch, and referent; foot function was categorized as over-pronated, over-supinated, and referent. The most extreme foot structure and function for each participant were used in analyses. Separate linear (continuous outcomes) and logistic (categorical outcomes) regression models were used to estimate the associations between foot type and physical function measures, adjusting for age, body mass index [BMI], sex, and race.

Results: 1571 participants had foot structure data and 1490 had foot function data (mean age 69 years, mean BMI 32 kg/m², 68% women, 30% African American). In standing, 22% had a low arch and 39% had high arch; during walking, 22% had an over-pronated foot and 31% had an over-supinated foot. Compared to the referent foot structure, higher FAOS-ADL scores (better physical function) were associated with a high arch in adjusted models, while a low arch was associated with worse physical performance on the chair stand and 8-foot walk tasks and with poorer balance (Table); these results were attenuated after controlling for age, BMI, sex, and race. Compared to the referent foot function, an over-supinated foot was associated with a faster 8-foot walk speed.

Conclusion: A high arch and an over-supinated foot were related to better lower extremity physical function. Longitudinal studies are needed to determine the effect of foot structure and function on changes in physical function and to assess interventions for modifying foot type (e.g., shoe orthotics) to limit physical decline in populations.

**Figure.** Change in gait function over two years, adjusting for baseline gait speed and PM monitoring time.
Adenosine A2A Receptor as a Potential New Therapeutic Target for the Prevention/Treatment of Osteoarthritis. Carmen Corcillo1, Anzazu Mediero2, Tuere Wider3 and Bruce N. Cronstein1. 1NYU School of Medicine, New York, NY; 2NYU School of Medicine, Division of Rheumatology, New York, NY.

Background/Purpose: Osteoarthritis results from trauma, mechanical factors or metabolic changes in bone and cartilage. Adenosine, acting via the A2A R, inhibits inflammation and plays a critical role in regulating bone factors or metabolic changes in bone and cartilage. Adenosine, acting via the A2A R, has chondroprotective effects in mice. A2AKO mice experience difficulty in movement, taking food and walking. We determined whether changes in their bone or joint structure or function could explain these changes.

Methods: Bone volume/total volume was determined with microCT analysis. Immunostaining for MMP-13 and Collagen-X was carried out. MicroCT analysis of knees was performed on the distal femur below the growth plate. Immunostaining for MMP-13 and Collagen-X showed an increase in Collagen-X and MMP-13 expression and release, with an increase in b-catenin expression. These effects are reversed by the A2A R antagonist, ZM241385.

Conclusion: Deficiency in adenosine A2A R leads to spontaneous osteoarthritis and stimulation of A2A Rs on chondrocytes diminishes changes associated with osteoarthritis, findings that suggest that A2A R may be novel targets for development of therapies to ameliorate or prevent osteoarthritis.

stained with safranin-O and fast green for histologic scoring of the entire articular surface, using the OARSI grading system. Some knee sections also were analyzed by immunohistochemistry (IHC) for expression and -phosphorylation of AMPKα and appearance of NITEGE neoepitope of aggrecanase activity.

**Results:** After DM M surgery, non-treated mice developed OA in the knee medial compartment, with a mean score of 3.72, indicated by loss of cartilage. In contrast, berberine significantly reduced spontaneous OA development, and particularly so in 24 months-old mice. The mean total joint scores for the berberine treated mice were 0.38 and 2.2 (p = 0.008), compared to non-treated mice at 24 months, 95% CI of difference: 0.84 to 7.97) at 18 and 24 months, respectively. Moreover, IHC analysis demonstrated that berberine inhibited both loss of phosphorylation of AMPKα and the appearance of NITEGE neoepitope in articular cartilage.

**Conclusion:** Maintenance of articular chondrocyte AMPK activity by berberine is therapeutically chondroprotective in vivo in mouse knee biomechanical injury and aging models. Targeted activation of AMPK by pharmacologic means, studied here using berberine, provides a novel approach to limiting OA development and progression in mice in vivo, and merits investigation in human OA.

**Syndecan-4 Regulates Chondrocyte Phenotype and Cartilage Homeostasis Via the WNT Signaling Pathway.** Charlotte Kimberley Clarke, Annelena Held, Richard Stange, Uwe Hansen, Lars Godmann, Jessica Bertrand, Thomas Pah, Giovanna Nalesso, Frank Echtenberger, Francesco Dell’Accio, Joanna Sherwood, Institute of Experimental Musculoskeletal Research, Barts and the London Queen Mary’s School of Medicine and Dentistry, London, United Kingdom.

**Background/Purpose:** Syndecan-4 (Sdc4), family member of type I transmembrane heparan sulfate proteoglycans (HSPGs), is a regulator of various cartilage-related processes including osteoarthritis (OA). Blockade of Sdc4 signaling protects mice from cartilage degradation in experimentally induced OA. OA is characterized by hypertrophic differentiation of chondrocytes and matrix remodeling. Various signaling pathways including the WNT signaling pathway may trigger this induction of chondrocyte differentiation. Experiments investigating the effect of different WNT3a concentrations on WT and Sdc4 deficient chondrocytes have emphasized a complex dialogue between canonical and non-canonical WNT pathways. We hypothesize that Sdc4 controls the chondrocyte phenotype by specific modulation of WNT signaling pathways.

**Methods:** In vitro analyses were performed using neonatal wild type (wt) and Sdc4-/- chondrocytes, or blocking antibodies against Sdc4. The influence of WNT3a on glycosaminoglycan (GAG) production was analyzed using alcian blue staining of micromass cultures. Expression of marker genes (e.g. aggrecan, collagen2, MMP13) was measured by quantitative RT-PCR. Effects of WNT3a on canonical and non-canonical WNT signaling were analyzed using Western Blot and luciferase reporter assay (AP-1, NFAT, TCF/Lef). The influence of WNT3a on the remodeling of the ECM was investigated by electron microscopy. Basal calcium concentrations without and upon WNT3a stimulation were examined using the Fura-2 method. In vivo relevance was investigated upon induction of OA using the DMM model.

**Results:** Micromass cultures revealed a higher basal GAG production in Sdc4-/- chondrocytes. WNT3a stimulation led to a decrease in GAG production in wt cells, which was absent in Sdc4-/- chondrocytes. qRT-PCR showed a 10X higher basal production of aggrecan and collagen2 in Sdc4-/- chondrocytes. WNT3a increased the expression of both genes in Sdc4-/- chondrocytes, MMP13 was significantly less expressed in Sdc4-/- chondrocytes and, unlike in wt cells, was not upregulated upon WNT3a stimulation. Western blot showed that β-catenin is strongly reduced and not upregulated upon stimulation with WNT3a in Sdc4-/- chondrocytes. LRPF was less phosphorylated and TCFα of promoter was less activated upon WNT3a stimulation in Sdc4-/- chondrocytes. pCamKII was increased under basal conditions, but decreased upon WNT3a stimulation in Sdc4-/- cells. The same effects on canonical and non-canonical WNT signaling upon WNT stimulation were obtained by using a blocking anti-Sdc4 antibody. Upon WNT3a stimulation, Sdc4-/- cells displayed a finer, more condensed and disorganized ECM structure compared

**Synovial Macrophages Promote TGF-β Activation after Intra-Articular Injections of Oxidized LDL in Naïve Murine Knee Joints, Preventing Production of Pro-Inflammatory Factors (IL-1β, IL-6) and Promoting Chondroprotection.** Annelena Held, Richard Stange, Uwe Hansen, Lars Godmann, Jessica Bertrand, Thomas Pah, Giovanna Nalesso, Frank Echtenberger, Francesco Dell’Accio, Joanna Sherwood, William Harvey Research Institute, Barts and the London Queen Mary’s School of Medicine and Dentistry, London, United Kingdom.

**Background:** Macrophages regulate joint pathology during experimental osteoarthritis (OA). Blockade of synovial macrophage-depleted joints. NITEGE expression was markedly increased (fold increase 1.92) in the synovial-cartilage contact areas after oxLDL injection (p<0.05).

**Conclusion:** Synovial macrophages promote anabolic effects after ox-LDL injections in knee joints, supporting earlier studies which show increased ectopic bone formation during LDL-rich conditions in experimental osteoarthritis. In absence of synovial macrophages, however, ox-LDL induces cell influx, production of pro-inflammatory mediators and aggrecanase activity.

to wt. Sdc4−/− chondrocytes had increased intracellular Ca2+ levels, which were reduced after 24h incubation with WNT3a. In vivo stainings confirmed in vitro results.

**Conclusion:** Sdc4 is a major regulator of the chondrocyte cellular response to WNT signalling through facilitating the induction of the canonical WNT signalling pathway. The blockade of Sdc4 protects from OA induced changes in chondrocyte phenotype by inhibiting WNT induced differentiation of chondrocytes.

**S100A9 Inhibitor Paquinimod (ABR-215757) reduces joint Destruction in Experimental Osteoarthritis and Blocks Activating Effects of S100A9 in OA Synovium.**

Peter L. van Lent1, Rik Schelbergen1, Arjen B. Blom1, Tomas Leandersson2, Helena Eriksson2 and Wim B. van den Berg3.

**Background/Purpose:** Synovial activation is present in more than 50% of osteoarthritic (OA) patients and it is thought to be involved in the development of OA pathology. Previously, we found that S100A8 and S100A9 are elevated in synovium of OA patients and that high S100A8/A9 serum levels correlate with 2-year progression of the disease. Furthermore, in experimental OA, S100A8/A9 proteins regulate cartilage degradation and synovial activation. Paquinimod is a quinoline-3-carboxamide compound with immune modulatory properties that is currently in clinical development for treatment of systemic sclerosis. It targets the carboxytail of the cytokine receptor-like Ig domain of the immune modulatory Tyro3, Axl, and MERTK (IIM) receptors (IIMRs). In this study we investigated the effect of paquinimod in two experimental osteoarthritis models differing in synovial activation and its effect on S100A9 stimulated OA synovium.

**Methods:** Collagenase induced OA (CIOA) was induced by two times intra-articular injection of 1U collagenase and DMM was induced by transection of the medial anterior meniscotibial ligament leading to destabilization of the medial meniscus (DM M), both in C57Bl16 mice. Paquinimod (3,75 mg/kg) was administered in the drinking water which was refreshed twice a week. Treatment started 4 days before induction of OA in both CIOA and DMM. Synovial thickening and cellularity was measured using an arbitrary score from 0–3. OA-like cartilage pathology was scored using a modified Prizker OARSI score. Osteophyte size was assessed by a blinded observer using imaging software. Human OA synovium was anonymously obtained from patients undergoing arthroplasty and stimulated with S100A9 and/or paquinimod. Proteins released by synovium were measured with Luminex.

**Results:** Paquinimod treatment of CIOA expressing high synovial activation resulted in significantly reduced synovial thickening (57%), osteophyte size at the medial femur (66%) and cruciate ligament formation (67%). Moreover, cartilage damage was reduced by paquinimod in CIOA at the medial tibia (47%) and femur (75%). In contrast, paquinimod did not reduce cartilage damage and reduced osteophyte size only slightly (only at the medial femur) in DMM, in which synovial activation is scant. In addition, human OA synovium comprising lining macrophages, was incubated with human S100A9 and/or paquinimod. S100A9 significantly upregulated pro-inflammatory IL-6, IL-8 and TNFα (9-fold, 12-fold and 20 fold increase respectively) and catabolic factors MMP1/1a, 3/1 (up to 2.5 fold). Adding paquinimod significantly inhibited S100A9-induced levels of IL-6 (35% reduction) and IL-8 (38% reduction) but not TNFα whereas MMP1 and MMP3 were reduced by 39% and 64% respectively.

**Conclusion:** Paquinimod reduces synovial activation, osteophyte formation and OA-like cartilage pathology in experimental OA with high synovial activation and ex vivo blocks pathological effects of S100A9 in OA synovium. Paquinimod could prove a very promising treatment for osteoarthritis patients expressing high synovial activation.

The Impact of Northern European Ancestry and Susceptibility Loci on the Risk of Lupus Nephritis.

University of California, San Francisco, Rosalind Russell / Ephraim P. Engleman Rheumatology Research Center, San Francisco, CA; Johns Hopkins University School of Medicine, Baltimore, MD; Feinstein Institute for Medical Research, Manhasset, NY; Genentech, Inc., South San Francisco, CA; Division of Rheumatology, University of Pittsburgh School of Medicine, Pittsburgh, PA; University of Pittsburgh, Pittsburgh, PA; University of California, Davis, CA.

Background/Purpose: Lupus nephritis (LN) has a higher prevalence among African Americans, Hispanics, and Asians compared to Caucasians. Significant differences in SLE severity also exist within continental groups, with northern European genetic ancestry conferring protection against autoantibody production and renal disease, which we have previously shown to be independent of socioeconomic status (SES). The goal of our study was to test whether the effect of northern European ancestry is mediated by known SLE risk alleles or recently identified LN susceptibility loci.

Methods: We studied 1142 SLE patients from four independent case collections with genotype data obtained from a previous genome-wide association study (GWAS). A set of continental and intra-European ancestry informative markers (AIMs) was analyzed using the program STRUCTURE to define the percent European and northern European ancestry for each subject. Subjects with <90% European ancestry were excluded. Multivariate logistic regression of LN risk was performed including percent northern European and other covariates (Table 1). Susceptibility loci were incorporated as potential mediators of the effect of genetic ancestry on the risk of LN. Forty-nine independent SLE risk alleles and 12 renal GWAS SNPs were included in the model of LN risk. A polygenic risk score (PRS), a statistical method for calculating the effect of many common variants in aggregate, was generated from a random 2/3 of individuals using the program PLINK to select 12,935 SNPs with evidence of cumulative association with LN (p < 0.05).

Results: The overall rate of LN in the study population was 27.3%. A 25% increase in the proportion of northern European ancestry was associated with a 16% reduction in the odds of having renal disease, after adjustment for disease duration and gender (OR 0.84, 95% CI 0.72-0.99, p = 0.04). Two previously reported SLE susceptibility loci (BANK1, HLA-DR3) and 7 of 12 LN risk SNPs were significantly associated with LN in our dataset. Adjustment for all 9 putative LN susceptibility loci did not substantially alter the association between northern European ancestry and LN (Table 1). Exploratory analyses incorporating the PRS were underpowered in our study but suggested that a more comprehensive set of genetic variants, as captured by the PRS, may explain more of the effect of Northern European ancestry on the risk of LN.

Conclusion: Northern European ancestry has a significant protective effect for renal disease among SLE patients of European ancestry; this effect is not fully explained by known SLE risk alleles.
appears to be independent of currently known SLE risk alleles and LN susceptibility loci, but may be partially explained by a PRS.

2956

Identification of Autoimmune Functional Variants Under Positive Selection in the Gullah African American Population from South Carolina. Paula S. Ramos1, Satria Sajuthi2, Jasmin Divers2, Yiqi Huang2, Ume Nayak2, Wei-Min Chen2, Kelly J. Hunt2, Diane L. Kamen2, Gary S. Gilkeson3, Jyotika K. Fernandes4, Ida J. Spruill5, W. Timothy Garvey1, Michelé M. Sale1, and Carl D. Lange4. 1Medical University of South Carolina, Charleston, SC; 2Wake Forest School of Medicine, Winston-Salem, NC; 3University of Virginia, Charlottesville, VA; 4University of Alabama at Birmingham, Birmingham, AL.

Background/Purpose: The reasons for the ethnic disparities in rheumatologic and autoimmune diseases (ADs) are largely unknown. We posit that population-specific selection influencing the allele frequencies at some loci contribute to ethnic disparities. Relative to other African Americans (AA), the Gullah population has lower European admixture and higher ancestral homogeneity from the Sierra Leone (SL) area in Far-West Africa. The shorter Gullah population has lower European admixture and higher ancestral contribute to ethnic disparities. Relative to other African-Americans (AA), the population-specific selection influencing the allele frequencies at some loci has the potential to elucidate AD risks in AA and help explain the ethnic disparity.

Methods: We computed the cross population extended haplotype homozygosity test (XP-EHH) to identify alleles with higher than expected frequency relative to their haplotype length in Gullah population controls (n=277) relative to SL population controls (n=400), to HapMap Phase II Africans (YRI, n = 203), and Caucasians (CEU; n=165). In total 679,513 SNPs met standard GWAS quality control criteria. Variants that met suggestive significance (XP-EHH > 4, P < E-04) were annotated and prioritized based on the potential impact of amino acid changes and regulatory functions using RegulomeDB and HaploReg, as well as overlap with immune/autoimmune-related genes and regions associated with ADs.

Results: Near the same number of loci showed suggestive evidence for selection between the Gullah and YRI (0.15%) of all SNPs, and Gullah and SL (0.14%), although only 106 SNPs in 12 regions showed evidence for selection in both comparisons. Fewer loci showed evidence for selection between Gullah and CEU (0.06%). This is reflected in the enrichment of different pathways in each comparison. Enhancer enrichment analysis of all suggestive SNPs revealed a significant enrichment of strongest enhancers in different pathways in each comparison. Enhancer enrichment analysis of all suggestive SNPs revealed a significant enrichment of strongest enhancers in different pathways in each comparison.

Conclusion: These results reveal several autoimmune-related genes harboring multiple SNPs with high regulatory scores based on the simultaneous presence of QTTLs, transcription factor binding and DNAse sites, including those showing evidence of selection between Gullah and YRI (CCR2, ADCY2, HLA, CD36, CAV1, GLG1, FXR2), Gullah and SL (CCR2, ADCY2), and Gullah and CEU (TET3).

2957

The Rheumatoid Arthritis -Risk Locus CCR6 and Its SNP-Dependent Response to Estrogen: A Possible Genomic Link Between Sex Hormones and the IL-17 Inflammatory Pathway. Ming-Fen Ho, None; R. M. Weinshilboum, None; L. Wang, None; T. Bongartz, None.

Background/Purpose: The CCR6-CCL20 mediated migration of Th17 cells to inflamed tissues may represent an important mechanism in the etiology of rheumatoid arthritis (RA). The CCR6 SNP rs3093023 is associated with RA disease risk. Variation in the CCR6 locus has been found to affect CCR6 expression and influence the IL17 serum concentration in RA patients (1). Importantly, an analysis of disease risk stratified by gender revealed opposing effects in Asian subjects: Specifically a CCR6SNP (rs3093024), which is in almost complete linkage disequilibrium with rs3093023, was associated with an increased risk of RA in women, but appeared to have a protective effect in men (2). We set out to determine whether variation in estrogen levels might influence the expression of CCR6 and other IL-17 pathway related genes. Furthermore, we aimed to clarify if such estrogen dependent regulation might be influenced by the presence of the variant CCR6genotype that is associated with RA disease risk in Europeans.

Methods: We genome-wide genotyped human lymphoblastoid cells using the Illumina 550K and 510S SNP beadchip and the Affymetrix SNP array 6.0. We then cultured eight LCLs homozygous for the wild-type (WT) SNP rs3093023 sequence and eight LCLs homozygous for the variant (V) allele with increasing concentrations of estradiol (E2). Expression of CCR6, CCL20, IL17A and IL17RA mRNA was measured by qPCR. We then performed siRNA knockdown experiments for CCR6 to explore the downstream effects. To predict putative estrogen receptor binding sites in the CCR6gene, we queried the TRANSFEC database. The functional relevance of putative binding sites was confirmed using ChIP assays.

Results: The basal expression levels of CCR6, CCL20, IL17A and IL17RA showed no differences when comparing cell lines with CCR6 WT versus V genotypes. Knockdown of CCR6 resulted in upregulation of CCL20 and IL-17A, but downregulation of IL-17RA expression. Treatment with E2 for 24 hours resulted in a significant increase in CCR6 expression in a dose-dependent manner, but only in cells with the V allele. CCL20, IL-17A and IL-17RA expression was also SNP-dependent in cells with the variant genotype. E2 treatment resulted in higher IL-17RA expression. Conversely, CCL20 and IL-17A expression decreased with estrogen treatment only in cells homozygous for the V allele. The TRANSFEC database predicted the presence of two estrogen response elements in the CCR6intronic region flanking the rs3093023 SNP. Chip assays demonstrated increased binding of estrogen receptor alpha when the V allele was present.

Conclusion: Our results indicate that a CCR6variant, which is associated with RA disease risk, can modulate the CCR6/CCL20/IL-17 axis in an estrogen-dependent manner. Enhanced binding of estrogen receptor alpha to the variant CCR6 genotype may contribute to the mechanism underlying this observation. Such a genomic link between variation in sex hormone levels and variation in cytokine/chemokine expression may provide new insights into the gender differences in RA prevalence and prognosis.

ments were defined by SNPs in proximity (−50 kb) to genes involved in 1. Urate transport: ABCG and SLC family members of urate-associated transporters and their direct connections in Inweb and String network databases\(^2\) (348 genes), 2. Urate metabolism: purine metabolism and glycolysis KEGG pathways (256 genes), 3. Immune-related: genes targeted by the Immunochip array (184 genes), 4. All other genomic regions, and 5. Intergenic regions. Polygenic scores based on GWAS P-value thresholds\(^3\) were calculated in Nurses Health Study (NHS) and the Health Professionals Follow-up Study (HPFS) samples, with incident gout cases having met ACR criteria for diagnosis, and were tested in multivariate analysis with sex, age, BMI and a 31 SNP urate genetic risk score as covariates.

**Results:** Polygenic scores were significantly associated with gout in metabolic genes (n=797 SNPs with \(P_{\text{GWAS}} < 10^{-8}\); \(P = 0.005\)) and other genomic regions (n=570,599 SNPs with \(P_{\text{GWAS}} < 0.5\); \(P = 0.001\)), with similar results for association with serum urate (\(P = 0.0025\) and \(P = 0.007\) for metabolic and other genes respectively). The immune gene compartment was not significant in gout (\(P>0.12\)) but was significant outside of the defined compartments also contributing. Excluding known loci, we found no additional evidence for polygenic variation in urate transport or immune-related functions contributing to serum urate or gout. Genomic compartments defined on function can provide additional discoveries and further biological insights into the etiologies of urate and gout.

**Conclusion:** Our results demonstrate an important role for metabolism in both serum urate and risk of gout, with genes outside of the defined compartments also contributing. Excluding known loci, we found no additional evidence for polygenic variation in urate transport or immune-related functions contributing to serum urate or gout. Genomic compartments defined on function can provide additional discoveries and further biological insights into the etiologies of urate and gout.
Methods: The Health Professionals Follow-up Study (HPFS) and Nurses’ Health Study (NHS) have systematically collected a wide range of exposures and health outcome data, including incident cases of gout, regularly for several decades. We ascertained incident gout cases using the American College of Rheumatology survey criteria. Using GWAS data from the two cohorts (4223 men from the HPFS and 6850 women from the NHS), we calculated a weighted genetic risk score (GRS) based on GUGC urate loci (possible range 0 to 58). Cox proportional hazards models were used to examine the association of GRS with GUGC urate loci and the risk of incident gout in these cohorts separately and together.

Results: Over a total of 262,805 person years, we documented 1081 confirmed cases of incident gout (727 in the HPFS and 354 in the NHS). The GRS ranged from 12.2 to 44.5 among our study participants. Increasing GRS scores were associated with an increasing risk of incident gout in both cohorts (P for heterogeneity < 0.17), and the pooled relative risks (RRs) for incident gout according to increasing GRS categories were 0.34, 0.66, 1.00 (referent), 1.37, 2.01, and 3.48 (P trend < 0.001 (Table 1)). Our analyses for individual loci (Table 2) showed that SLC2A9, ABCG2, and GCKR were significantly associated with the risk of incident gout in each cohort as well as in the pooled cohort. TME171, SLC1A7, INHBC, VEGFA, and UBE2Q2 were moderately associated only in men (HPFS), and PRKAG2, B4GALT1, MAF, and HLF were modestly associated only in women (NHS). Heterogeneity between the sexes of these loci was significant for INHBC, PRKAG2, B4GALT1, and HLF.

Conclusion: These two large prospective cohort studies confirm that the urate GRS scores are strongly associated with the risk of incident cases of gout among men as well as among women. SLC2A9, ABCG2, and GCKR were most strongly associated with the risk of incident gout, and nine additional urate loci are more modestly associated with the risk as well.

Methods: Summary level statistics from the Kottgen et al. GWAS were used in collaboration with the Global Urate Genetics Consortium. The Genome-Wide Complex Trait Analysis (GCTA) package was used to test for association conditional on the lead single nucleotide polymorphism (SNP). A total of 9713 HapM ap2 genome-wide imputed genotypes from European participants of the Atherosclerosis Risk in Communities study were used as a reference. An independent effect at each locus was defined as an association signal, after conditional analysis, of P < 0.05 divided by the number of SNPs analyzed. Further rounds of analyses were conducted if SNPs remained significant after conditioning. The percent variance explained for each SNP was calculated by the formula b^2*(var(X)/var(Y)).

Conclusion: The independent effects provide evidence for multiple etiological variants at the serum urate loci in Europeans, emphasizing the complex genetic control of serum urate levels. These results are an important initial step in fine-mapping the causal variants. For example, one of the independent effects at SLC2A9 (rs3775948) was the lead SNP in a urine GWAS in East Asian individuals, indicating both shared and unique genetic effects between East Asians and Europeans. The use of multiple ancestral groups will be important in future fine-mapping.
Background/Purpose: Gout results from innate immune response to monosodium urate (MSU) crystals that form in the context of supersaturation of urate. Identification of genetic risk factors for hyperuricemia and the MSU immune response is therefore important for insight into the etiology of gout. Genome-wide association analyses have provided significant insights into the causes of hyperuricemia, however there are no confirmed loci for normouricemia. In addition, including MSU crystals. To replicate, we tested rs2149356 for association with gout in 2,501 European and Polynesian cases and 9,105 controls.

Methods: All gout cases were clinically ascertained according to the American Rheumatism Association criteria. European cases (n = 1614) were recruited from New Zealand (n = 647), by the Epiqgroup consortium within the American Crystal Network (n = 779) and by the Arthritis Genomics Recruitment Initiative in Australia (AGRA; n = 1188). European normouricemia (n = 8017) were recruited from NZ (n = 875) and sourced from the Atherosclerosis Risk in Communities (n = 4143) and Framingham Heart (n = 2999) studies. There were 872 New Zealand Māori and Pacific Island (Polynesian) cases and 1088 controls.

Genotyping of rs2149356 was done by Taqman in the New Zealand samples and imputed in A RIC and FH5 from a Affymetrix genome-wide data. Association analysis was done by STATA and adjusted by age, sex and (as appropriate) estimate of Polynesian ancestry.

Results: Using controls unstratified for urate status, there was no evidence for allelic or genotypic association in the European sample sets (Table). However the TT genotype was associated with gout in Polynesians (OR TT genotype = 0.68, P = 0.012). Comparison of cases to hyperuricemic controls revealed evidence for association with gout in Europeans (OR G allele = 1.26, P = 0.005; OR T allele = 1.63, P = 0.009), but weakened evidence for association in Polynesians (OR G allele = 0.88, P = 0.25; OR T genotype = 0.77, P = 0.21).

Conclusion: The previous report of association of TL4 with gout in Chinese 2 was replicated in Europeans with the T allele of rs2149356 conferring risk in both populations. Evidence for association was weaker in Polynesians, with the G-allele conferring risk. The strengthening of association in Europeans using hyperuricemic controls is consistent with a role for this locus in gouty inflammation in the presence of hyperuricemia. Subject to further replication, TL4 represents the first replicated non-urate serum genetic risk locus identified in gout, and provides support for a role of TL4 in the etiology of gout.

2594 Association Analysis of Apolipoprotein B and Very Low-Density Lipoprotein with Hyperuricemia and Gout. Humaira Rasheed1, Angela Hsu1, Nicola Dal'beth2, Lisa K. Stamp3, Sally McCormick1 and Tony R. Merriman1.

1University of Otago, Dunedin, New Zealand, 2University of Auckland, Auckland, New Zealand, 3University of Otago, Christchurch, New Zealand.

Background/Purpose: Gout results from innate immune response to monosodium urate (MSU) crystals deposited in joints. Increased very low-density lipoprotein (VLDL) has been associated with gout. Apolipoprotein B (apoB), present on VLDL, regulates neopterin response to MSU crystals. ApoB has been positively associated with gout and the apoB mRNA-editing gene, AICF, is associated with urate levels. However the relationship of apoB and VLDL with gout in the presence of hyperuricemia has not previously been tested. Therefore we tested the association of VLDL and apoB with gout in the presence of hyperuricemia (HU).

Methods: New Zealand European (n = 90) and Māori and Pacific Island (Polynesian) (n = 90) male gout case and control sample sets were divided into normouricemia (NU: serum urate <411 mmol/L), asymptomatic hyperuricemia (HU: serum urate =411 mmol/L) and gout groups. Gout was classified using the 1997 American Rheumatism Association criteria. Size exclusion chromatography and enzyme-linked immunosorbant assay were used to measure VLDL and apoB. Multivariable linear regression was used to assess the risk of gout and HU per unit change in VLDL and apoB.

Results: Increased levels of VLDL triglycerides (Tg) were observed in the gout sample set compared to NU and HU in European (P = 0.02 and 2×10−4, respectively) and Polynesian subjects (P = 0.042 and 0.019, respectively). This increase was driven by overproduction of VLDL particles in the European subjects and by the Tg-enrichment of existing VLDL particles in the Polynesian subjects. Each mmol/L increase in VLDL Tg was significantly associated with gout in the presence of HU in Europeans, with a similar trend
in Polynesians (OR = 6.82, P = 0.017 and 2.85, P = 0.066, respectively). Each 
μmol/L increase in ap08 was associated with a decreased risk of HU (OR = 0.47; P = 0.046) and, conversely, with increased risk of gout in the presence of HU (OR = 4.79; P = 0.005: Table 1) in combined sample set.

**Conclusion:** Increased VLDL Tg is associated with the risk of gout in the presence of HU. If genetic approaches indicate evidence for causality of VLDL in gout, this would provide further support for clinical trials examining the effects of fibrates as a treatment option in gout.

**Genome-Wide Association Analysis of Pain Reduction in Rheumatoid Arthritis Patients Treated with TNF Inhibitors.** M. A. van de Laar1, M. A. Umicevic-Mirkov2, Sophie B. Krintel3, Julia Johansen4, Corinne Michel-Richard5, Henrik Kalberg6, Hans Schefler7, Wieske Kiewit1, Maartje van de Laar1, Piet L. C. M. van Riel1, X. Mariette8, Saediddin Saevardsdottir9, Marieke J. H. Coenen1, Piet L. C. M. van Riel, J. H. Mariette, K. Etterw, S. Vermeulen8, I. Albers1. 1Radboud university medical center, Nijmegen, Netherlands, 2Copenhagen University Hospital, Glostrup, Glostrup, Denmark, 3University of Copenhagen, Frederiksberg, Denmark, 4Université Paris-Sud 11, Bicêtre Hospital, Kremlin Bicêtre, France, 5Karolinska University Hospital, Stockholm, Sweden, 6University Twente & Medisch Spectrum Twente, Enschede, Netherlands, 7Paris-Sud University, Paris, France, 8Karolinska University Hospital and Karolinska Institutet, Stockholm, Sweden, 9DANTIO, Center for Rheumatology and Spine Diseases, Glostrup Univ Hospital, Glostrup, Denmark.

**Background/Purpose:** Gout is a common inflammatory arthropathy with a high prevalence in rheumatoid arthritis (RA) patients treated with TNF inhibitors (TNFi). Due to the high frequency of concomitant osteoarthritis (OA), therapeutic options are limited. We aimed to identify and replicate genetic factors predicting pain reduction upon TNFi treatment in patients with RA using genome-wide association approach.

**Methods:** We included 508 TNFi treated RA patients. Association analysis of change of visual analogue scale of pain (VAS-pain) after 14 weeks of treatment was performed on imputed genome-wide genotyping data under additive genetic model with adjustment for baseline VAS-pain. We also conducted a meta-analysis including 1287 RA patients. Gene-based analysis was performed using VEGAS.

**Results:** No findings reached the threshold for genome-wide significance (P-value<1×10^-8) in the discovery cohort. Meta-analysis revealed 213 SNPs suggestively associated (P<10^-4) with change in VAS-pain after fourteen weeks of TNFi treatment. The most significant SNP rs2295739 (p=2.21×10^-6), located ~35kb upstream from the KCNK19 gene. Which belongs to a family of genes involved in sensory perception. The top hit in the gene-based analysis was RET, known to regulate ion channels and receptors participating in detection and transduction of sensory stimuli. Besides Ret-deficient mice show elevated pain responses.

**Conclusion:** We have identified several suggestive genomic regions, further studies are required to validate if these regions play a role in pain reduction upon TNFi treatment.

Patient Reported Pain By the PainDetect Questionnaire Reveals Multimodal Elements to Pain Perception in Rheumatoid Arthritis. Saja Ahmed1, Tejal Magan2, Mário Vargas3, Abiola Harrison3 and Nidhi Sofat4. 1St George’s, University of London, London, United Kingdom, 2St George’s University of London, London, United Kingdom.

Background/Purpose: Rheumatoid arthritis (RA) is an inflammatory autoimmune condition typified by systemic inflammation targeted towards synovial joints. Inhibition of pro-inflammatory networks by disease-modifying anti-rheumatic drugs e.g. methotrexate and biologic therapies including TNFα inhibitors, often leads to suppression of disease activity. However, despite the era of widespread use of disease-modifying treatments, there remain significant groups of patients who continue to experience pain.

Methods: Our study formulated a pain assessment tool to be used in the arthritis clinic to assess feasibility of measurements including the visual analogue scale (VAS) for pain (range 0–100 mm) and painDETECT questionnaires (range 0–38) to evaluate neuropathic features of pain in people with established RA (n=100). Clinical measures of disease activity (DAS28), disease-modifying medication use, body mass index (BMI) and worst pain ever were also recorded. Continuous data was described and analysed using parametric statistics, with ANOVA and Chi-squared tests for groups with 3 or more categories.

Results: We found that participants with RA reported relatively high pain levels, despite widespread use of disease-modifying drugs (Table 1). The majority, 54%, reported ‘severe pain’ on the visual analogue scale (VAS), which identifies people with a VAS of ≥41–100 mm as having the highest severity of pain. The mean DAS28 in the group was 2.09 ± 0.96. The majority of subjects had duration of diagnosis greater than or equal to 5 years (84%), suggesting that pain was a persisting symptom despite sustained use of disease-modifying agents and a DAS28 score suggesting clinical remission. All participants evaluated had been stable on DMARD therapy for at least 3 months prior to completing the study and had not required a change in their treatment, or addition of corticosteroid therapy during that time. The majority of participants were being treated with disease-modifying drugs, including the commonest agent, methotrexate (82%). Using the painDETECT questionnaire, 67% of patients had unlikely neuropathic pain. A significantly high proportion of 28% subjects had possible neuropathic pain and 5% had features of likely neuropathic pain by painDETECT scoring. We found a positive correlation between VAS and painDETECT (r² = 0.757). Of note, the group who had likely or probable neuropathic pain also showed significantly increased pain perception by VAS (p < 0.01). Subjects who were clinically obese (BMI > 30) had statistically higher proportions of pain reporting (VAS 89.0 ± 0.7) compared with subjects who had a normal BMI (VAS 45.2 ± 21.8), p < 0.05.

Conclusion: Our findings suggest that multimodal features of pain perception exist in RA, including neuropathic and sensitisation elements, perhaps explaining why a subgroup of people with RA continue to experience ongoing pain, despite their apparent suppression of inflammation.

Improvement Following Total Knee Replacement (TKR) Surgery: Exploring Preoperative Symptoms and Change in Preoperative Symptoms. Ernest R. Vina1, Michael J. Hannon2 and C. Kent Kwoh3. 1University of Pittsburgh and VA Healthcare System, Pittsburgh, PA, 2University of Pittsburgh School of Medicine, Pittsburgh, PA, 3University of Arizona, Tucson, AZ.

Background/Purpose: Few have examined the trajectories of preoperative health-related quality of life (HRQOL) measures in osteoarthritis (OA) patients who undergo TKR. Yet, the type and rate of preoperative decline may predict the outcomes of TKR. The objectives of the study are to determine whether changes in preoperative HRQOL measures are associated with improvement after TKR and to identify important predictors of clinically significant improvement.

Methods: Data from people who underwent TKR were obtained from the Osteoarthritis Initiative (OAI), a study which annually assessed participants. T0 was the assessment prior to TKR while T-1 was the assessment prior to that. T+2 was the second assessment after TKR. We compiled data on OA-related symptoms (i.e. pain/aching/stiffness most days of the month in the last year), the WOMAC, activities, and radiographic severity (i.e. Kelgren-Lawrence grade, KLG). We defined clinically significant improvement as improvement in WOMAC total score ≥ the minimal important difference (0.5 standard deviation of mean change in the study data) between T0 and T+2. After conducting bivariate tests for differences, logistic regression models were performed to evaluate the relationship between improvement and preoperative measures. Only variables associated with improvement at p ≤ 0.2 in a series of stepwise regressions were included.

Results: Our sample consists of 211 improved & 58 unimproved patients. Improved, compared to unimproved, patients had higher preoperative (T0) WOMAC pain (39.31 ± 17.86 vs. 22.73 ± 17.92, p < 0.001), disability (39.17 ± 15.08 vs. 18.23 ± 16.86, p < 0.001) and stiffness (46.45 ± 20.21 vs. 27.37 ± 20.47, p < 0.001) scores in the index knee (i.e. TKR knee). Those who had improvement were more likely to report OA-related symptoms in the index knee (96.68% vs. 77.59%, p < 0.001). They also had greater worsening of their WOMAC pain (9.65 ± 19.53 vs. 2.48 ± 13.19, p < 0.002), disability (9.87 ± 17.22 vs. 0.16 ± 13.38, p < 0.001) and stiffness (9.11 ± 23.23 vs. -0.24 ± 20.34, p = 0.009) scores from T-1 to T0 in the index knee.

Conclusion: Pain measures as predictors of improvement in our multivariate model included: Higher WOMAC disability (OR 1.09, 95% CI [1.05–1.13], p < 0.001), presence of OA-related symptoms in the index (OR 7.13, 95% CI [1.77–28.67], p = 0.006) but absence in the contralateral (OR 8.07, 95% CI [2.75–23.74], p < 0.001) knee, exposure to frequent knee bending (OR 3.01, 95% CI [1.02–8.87], p = 0.045), having a KLG of 4 (vs. 0, 1, 2 or 3) in the contralateral (OR 4.40, 95% CI [1.24–15.56], p = 0.022) and index knee (p = 0.124), and worse SF-12 Mental Health score (p = 0.209).

Mortality after Knee Replacement Surgery for Osteoarthritis in a Population-Based Propensity-Score Matched Cohort. Devyani Misra1, Tuhina Neogi1, Na Lu1, David T. Felson2, Thomas Einhorn1, Hyon Choi2, Jessica Maxwell3 and Yuqing Zhang4. 1Boston University School of Medicine, Boston, MA, 2Harvard Medical School, Boston, MA, 3Boston University, Boston, MA.

Background/Purpose: Knee replacement (KR) surgery for osteoarthritis (OA) provides improvement in symptoms and function. Whether these improvements translate into survival benefit has been unclear, likely related to selection of healthier patients for surgery, exclusion of the post-operative immune response, and inadequate length of follow-up in prior studies. The purpose of this study was to determine risk of mortality related to KR by comprehensive adjustment for confounders using a propensity-score (PS) matched cohort approach and long follow-up.

Methods: Participants ages 50–89 years with a diagnosis of knee OA (from Read Codes) were included from The Health Improvement Network....
(THIN), an electronic medical records database representative of the UK general population. High risk subjects who are less likely to be surgical candidates (BMI > 40, history of joint infection, high risk cancers (pancreatic, esophageal, gastric or other metastatic), end-stage renal disease on dialysis, use of nasal cannula oxygen, or DMARD therapy) were excluded. PS for KR was calculated using logistic regression with KR as the dependent variable and the confounders listed in the table as independent variables, that reflect indications for KR and risk for poor outcomes. One year cohort-accrual blocks were matched within each KR subject and a random date within the cohort accrual block for non-KR subjects, and continued until death or censoring. We examined the association of KR with mortality by calculating crude incidence rates (IR) and Hazard ratios (HR) using Cox proportional hazard regression. We also examined the association stratified by age category (<70 years, 70–80 years, 80+ years) and within percentile categories of the PS.

Results: There were 14,675 pairs of subjects with knee OA (mean age 71.8 years; mean BMI 29.0 kg/m²) in the PS-matched cohort. The follow-up years were 63,669 and 60,582 for matched KR and non-KR subjects, respectively. Overall there was a 31% lower risk of mortality among subjects with KR (HR 0.69, 95% CI 0.64–0.75). The lower risk remained in subjects <70 years but no such relation was noted in subjects ≥70 years (table). The crude IR for mortality among KR subjects decreased as PS percentile category increased, while no such trend was noted for the non-KR subjects. Mortality risk was lowest (HR 0.29, 95% CI 0.13–0.63) in the highest PS percentile (>98%) category (table).

Conclusion: We found KR to be protective for mortality risk among subjects <70 years and among those with the highest propensity for KR. Although a protective effect of KR cannot be ruled out, there likely remains confounding by indication despite comprehensive adjustment of covariates. Patients, physicians, and surgeons consider additional factors in performing KR that are not adequately captured within administrative databases.

Table: A association of Knee Replacement Surgery and Mortality Risk, stratified by age and by percentiles of propensity scores, in a propensity-score matched cohort of men and women with knee osteoarthritis.

Patient's Self-Monitoring Via Smartphone: The Compass Study Correlation Between Patient Self-Assessment of Rheumatoid Arthritis Disease Activity Via Smartphone Technology and Physicians' Validated Scores, Ruediger Mueller1, Ulrich Walker2, Diego Kyzurz3, Robert Theiler4, Adriaan Forster5, Fabiana Ganz6 and Patrick Dufner7. 1Kantonspital St. Gallen, St. Gallen, Switzerland, 2Department of Rheumatology, Basel University, Basel, Switzerland, 3Universitats Hospital, Basel, Switzerland, 4Tirrelli spital, Zurich, Switzerland, 5Spital Thurgau AG, Diessenhofen, Switzerland, 6Abov not, Baar, Switzerland.

Background/Purpose: In clinical practice, patients with RA are usually seen every 3 to 6 months1. Although desirable, monthly visits with assessments of disease activity are often not possible due to limited physician resources2. However, patients increasingly wish to be actively involved in treatment decisions. Therefore, the development of an internet-based tool for disease activity score assessments by patients could represent an innovative solution. The CoMPASS study aims to demonstrate a correlation between the patient assessments of RA disease activity via smartphone and the disease activity done by the physician using traditional scores.

ACR Concurrent Abstract Session

Rheumatoid Arthritis - Clinical Aspects VII: New Aspects of Monitoring Disease Wednesday, November 19, 2014, 9:00 AM–10:30 AM

S1298
Methods: Adult RA patients under current non-intravenous DMARD treatment were included in the prospective, single-arm, multicentre study. Patients were equipped with smartphones and educated to use a web application (WebApp) for self-assessment. Patients were assessed clinically by the treating physician at baseline. The assessment included joint counts, global assessment, laboratory values, along with simultaneous WebApp questionnaires (RAPID3/4) that were filled in by the patient. During the subsequent 3 months, patients were asked to fill in the WebApp questionnaire at least once a week. Descriptive statistics for RA disease activity according to the WebApp and rheumatologist evaluation at the baseline visit were analysed with the Pearson Correlation. Sensitivity analysis was performed.

Results: Ninety patients were recruited in five Swiss clinics (mean: SD); RA duration: 7.1 years (8.6); age: 54.7 years (13.5); 60% male. The data showed a strong correlation between patient and rheumatologist assessment of disease activity when comparing RAPID3 with DAS44 at baseline (Fig 1, R = 0.60; 95% CI 0.43 - 0.73), CDAI (R = 0.53; 95% CI 0.34-0.68) and SDAI (R = 0.49; 95% CI 0.28 - 0.65). The sensitivity analysis demonstrated that this correlation was independent of disease characteristics, treatment type, demographics, and centre effects, as well as unaffected by a delay of the smartphone data entries up to 7 days after baseline assessment by the rheumatologist. A similar correlation was seen for RAPID4 and DAS44 (R = 0.61; 95% CI 0.45 - 0.74), CDAI (R = 0.55; 95% CI 0.37 - 0.70) and SDAI (R = 0.50; 95% CI 0.30 - 0.66).

Conclusion: In this multicentre study patients’ self-assessment of disease activity (RAPID3 and 4) correlated strongly with that of rheumatologists (DAS44, CDAI, SDAI), indicating that patients are able to self-assess their disease activity. This provides a rationale to further explore the use of smartphone technology for tight disease monitoring in order to help the rheumatologist to optimize RA management. Whether or not the use of a WebApp for self-assessment will lead to better treatment outcomes will have to be shown in future studies.

Figure 1: Pearson Correlation at Baseline - RAPID3 and DAS44 at baseline as primary endpoint.

Elevations of Certain Memory-Effecter T Cell and Inflammatory Monocyte Subpopulations in Rheumatoid Arthritis Are Associated with the Presence of Subclinical Coronary Artery Atherosclerosis. Robert Winch-ester, Jon T. Giles, Simona Nativ, Hui-Zhu Zhang, Kendall Downer and Joan Balthazard Columbia University, New York, NY, “Morristown Medical Center, Morristown, NJ.

Background/Purpose: Factors that identify cardiovascular disease (CVD) fully in RA are lacking. Peripheral blood mononuclear cell (PBMC) subsets in RA patients differ markedly, on average, from non-RA controls with respect to memory T cell subset differentiation to memory effector status and in the degree of circulating PBMCs reflecting differentiation to memory effector status/acquisition of NK receptors and higher levels of intermediate (inflammatory) monocytes. We hypothesized that elevations in these subpopulations would distinguish those with subclinical atherosclerosis.

Methods: Patients with RA and no clinical CVD underwent cardiac computed tomography (CT). Coronary arterial calcium (CAC) was quantified by the Agatston method. PBMC subsets were assessed by multiparameter flow cytometry. Multivariable linear and logistic regression were used to assess the associations between PBMC subpopulations and CAC, adjusting for relevant confounders associated both with PBMC subsets of interest and CAC. The area under the receiver operator curve (AUC) was used to estimate the contribution of covariates on the prediction of any CAC.

Results: 72 RA patients [mean age 54±14 years; 64% female; shared epitope positive 64%, median RA duration 6.6 years; median DAS28-3.9; current biologic use in 31%] were studied. Any CAC [CAC >0] was observed in 34%. In univariate analyses, compared with patients with no CAC, those with CAC had significantly higher percentages of circulating CD4 T cell subsets denoting activation (CD4+HLA-DR+, CD4+CD28+HLA-DR-), differentiation to memory effector (CD4+CD28+HLA-DR+CD4+CD56+CD57+), and acquisition of NK receptors (CD4+CD56+CD57+) and similar increases of analogous CD8 T cell subsets, along with increases in the proportion of intermediate CD14+CD16 monocytes. The CD4 and CD8 subsets were highly correlated, while the CD14+CD16+ monocyte subset was independent of the CD4 and CD8 subsets. In multivariable models including all non-collinear PBMC subsets of interest, only levels of CD4+CD56+CD57+ T cells and CD14+CD16+ monocytes remained significantly associated with the presence of CAC after adjusting for relevant RA and CVD risk factors (Figure). CRP, serum IL-6 and DA528 were not associated with CAC. The AUC for any CAC for the model containing only the two PBMC subsets of interest was 0.76 (95% CI: 0.64 - 0.87), this increased to 0.89 (95% CI: 0.82 - 0.96) with the addition of age and systolic blood pressure to the model. Neither PBMC subset of interest was associated with the extent of CAC within those with a positive CAC score.

Conclusion: Subclinical atherosclerosis was robustly associated with levels of circulating PBMCs reflecting differentiation to memory effector status/acquisition of NK receptors and higher levels of intermediate (inflammatory) monocytes, independent of demographics, CVD risk factors, and, importantly, RA disease activity and severity. These factors may account for a portion of the unexplained contributors to enhanced atherogenesis in RA.

The Multi-Biomarker Disease Activity Score As a Predictor of Radiographic Progression in a Registry of Patients with Rheumatoid Arthritis. Eric H. Sasso1, George Wu2, CC Hwang3, Michael E. Weinblatt2, Nancy A. Shadick2, Claire Alexander1 and Oscar Segurado1. 1Crescendo Bioscience Inc., South San Francisco, CA, 2Brigham and Women’s Hospital, Boston, MA.

Background/Purpose: This study evaluated the association between baseline disease activity, as assessed with the multi-biomarker disease activity (M BDA) blood test, CRP or clinical measures, and the rate of radiographic progression over 2 years for patients with rheumatoid arthritis (RA) receiving stable therapy in the Brigham and Women’s Hospital Rheumatoid Arthritis Sequential Study (BRASS) Registry.

Methods: M BDA scores, CRP, DAS28-CRP, CDAI, RAPID3, and radiographic progression were analyzed at baseline (defined as the initial visit in the BRASS registry), for 143 patients with RA who had received a stable treatment, i.e., with no addition or removal of DMARDs and irrespective of dosing, over 2 years. Radiographs of hands and wrists only, taken within 3 months of baseline in BRASS and 2 years later, were evaluated to determine the change per year in total Sharp score (ΔTSS). Radiographic progression (RP) was defined as ΔTSS > 3 per year over 2 years. Predictive performance was assessed using AUROC. Associations with RP were evaluated using univariate and multivariate logistic regression adjusted for potential founders.

Results: For 143 patients, mean age and disease duration were 59 and 18 years, respectively, with 84% female, 80% seropositive (RF+ and/or anti-CCP+), and 52% receiving MTX/non-biologic DMARD monotherapy, 19% a TNF inhibitor alone, 27% both in combination, and 2% not on any DMARD therapy. Mean baseline values were MBDA score = 39, CRP = 0.86 mg/dL.
DAS28-CRP = 4.1, CDAI = 24.8, RAPID3 = 8.1 and TSS = 6.8. RP was observed in 18% (26/143) of patients. Better predictive accuracy for RP was observed for baseline MBD A score (AUROC = 0.75), compared with baseline clinical CRP (AUROC = 0.71), DAS28-CRP (AUROC = 0.62), CDAI (AUROC = 0.50) or RAPID3 (AUROC = 0.50). Adjusting for BMI and baseline TSS, the significant independent predictors for RP were MBD A score (OR 0.99, 95% CI 1.54–3.6, r = 0.28–0.35), DAS28 (AUROC = 0.71, 95% CI 1.46–3.62), and DAS28-CRP (AUROC = 0.74, 95% CI 1.04–3.94), but not DAS2 (OR = 0.46, 95% CI 0.2–2.41) and RAPID3 (OR = 0.49, 95% CI 0.61–3.55). For patients with low CRP (≤1 mg/dL), at baseline, RP was observed in 34.8% (8/23) with high MBD A score (>44) versus 8.1% (7/86) with low/moderate MBD A score (<44) (p = 0.003).

Conclusion: Baseline MBD A score was a better predictor of radiographic progression over 2 years than CRP, DAS28-CRP, CDAI or RAPID3 in patients with RA on stable therapy from the BRAS5 registry.

2974 Multi-Biomarker Disease Activity Score Is Associated with Power Doppler Ultrasound in Patients with Rheumatoid Arthritis in Low Disease Activity State.

M argaret H. Ma,1, Toby Garrood,1, Wanying Li,1, Nadine A. Defranoux,2, Gabrielle H. Kingsley,1, Andrew P. Cope1 and David L. Scott1.

1King’s College Hospital, London, United Kingdom, 2Guy’s and St. Thomas’ Foundation Hospital NHS Trust, London, United Kingdom, 3Crescendo Bioscience Inc., South San Francisco, CA, 4King’s College London, London, United Kingdom, 5King’s College London, Department of Rheumatology, London, United Kingdom.

Background/Purpose: Rheumatoid arthritis (RA) patients increasingly achieve clinical remission with intensive treatment regimens. However, ultrasound (US) subclinical synovitis has been reported in remission states. The multi-biomarker disease activity (MBDA) blood test assesses overall RA disease activity.

The purpose of this study was to evaluate associations between US signals, MBD A score and its component biomarkers in the REMIRA cohort, a 1-year prospective observational study of patients with RA in low disease activity.

Methods: We studied 95 patients with RA on stable therapy for ≥6 months with DAS28 = 3.2 for ≥1 month. Clinical measurements and serum samples were collected every 3 months for 1 year and US were conducted at baseline (BL) and 1 year. MBD A scores (range 1–100) were calculated from the serum concentrations of VCAM-1, EGF, VEGF-A, IL-6, TNF-R1, YKL-40, MMP-1, MMP-3, IL-1, leptin, resistin, SAA and CRP using the validated Vectra® DA algorithm. MBD A disease activity thresholds have been defined as remission (≤2.6), low (2.6–29), moderate (30–44), and high (>44). Power doppler (PD) and synovial hypertrophy (SH) of bilateral MCP joints and wrists were assessed by the same sonographer on the same machine and with MCP and PIP joints rarely involved (both 2% respectively). A higher frequency of signal, no intra-articular flow to 3+ (44) was counted. Of the 101 patients included, median (IQR) age was 54 (48, 63) years old. Clinical characteristics such as age, sex and seropositivity were observed. Patients with low disease activity had high PDUS-DAS28 (p = 0.001), ESR (p = 0.002) and were more likely to receive combination triple therapy (DMARDs) (p = 0.008). Residual large joint involvement was significantly associated with mHAQ > 0.5 (p = 0.03), lower SF12 physical component scores (p = 0.02) and higher RAID score (p = 0.001).

Conclusion: Ultrasound PD and SH signals could be detected in most RA patients of the REMIRA cohort. After applying a modified, more stringent, scoring system, 21% to 31% had detectable US signals. We have shown, for the first time, significant correlations with PD and mPD scores for MBD A scores and some of its component biomarkers. Correlations were also found with DAS28 and SJC28. Remission by MBD A score was significantly associated with mPD = 0. These results suggest that MBD A score detect low grade inflammation and subclinical synovitis in patients with RA in clinical remission or low disease activity.

Disclosure M. H. M. None; T. Garrood, None; W. Li, None; A. Cope, None; D. L. Scott, None.

2975 Residual Large Joint Synovitis By Power Doppler Ultrasound Is Associated with Higher Disease Activity and Significant Impact of Disease in Multi-Ethnic Asian Patients with Established Rheumatoid Arthritis.

Y. Xiao Guo1, Manjari Lahiri2 and Peter Chevron1.

1Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore, 2Division of Rheumatology, National University Hospital, Singapore, Singapore.

Background/Purpose: Regular monitoring of disease activity with appropriate modification of disease-modifying anti-rheumatic drug (DMARD) therapy results in improved radiographic and functional outcomes in patients with rheumatoid arthritis (RA). Large joint involvement has been shown to impact significantly on both disease activity and disability. Power Doppler ultrasound (PDUS) can effectively detect subclinical active synovitis not appreciated by clinical examination. The objective is to evaluate the presence of residual large joint disease in established RA patients in a multi-ethnic Asian cohort using PDUS as the reference standard, and whether there is increased impact and disability.

Methods: Patients with established RA (ACR 1987 criteria) and stable disease were recruited as part of a randomized controlled single centre study, evaluating the use of ultrasonography feedback as training tool for patient self-assessment of synovitis. At baseline, 28 joints (2 shoulders, 2 elbows, 2 wrists, 10 MCP, 10 PIP, 2 knees) of each patient were assessed for synovitis in B-mode (from 0 = absence of synovial thickening to 3 = marked synovial thickening) and PDUS (from 0 = absence of signal, no intra-articular flow to 3 = marked signal in more than half of the synovial area). Semi-quantitative grade ≥1 on PDUS was considered as active synovitis. Patients with residual large joint disease (shoulders, elbows, knees) on PDUS were evaluated for differences in baseline demographics, disease activity, physical function (modified Health Assessment Questionnaire, mHAQ) and SF12-physical component score) and impact of disease (Rheumatoid Arthritis Impact of Disease Score, RAID) with patients that did not have large joint involvement. Measures of association were evaluated using logistic regression.

Results: Of the 101 patients included, median (IQR) age was 54 (48, 63) years old. Clinical characteristics such as age, sex and seropositivity were observed. Patients with low disease activity had high PDUS-DAS28 (p < 0.001), ESR (p = 0.002) and were more likely to receive combination triple therapy (DMARDs) (p = 0.008). Residual large joint involvement was significantly associated with mHAQ > 0.5 (p = 0.03), lower SF12 physical component scores (p = 0.02) and higher RAID score (p = 0.001).

Conclusion: Multi-ethnic Asian RA patients with relatively stable established disease have a high proportion of residual PDUS large joint activity that significantly impacts on patients. Physicians should aggressively treat this subset of patients with either systemic/local therapies to prevent further disability.

Lung Ultrasonography for Interstitial Lung Disease in Rheumatoid Arthritis. Comparison with Usual Detection Algorithms in Clinical Practice. Marco Antivallie, Michele Chevallard, Michele Battelino, Maria Chiara Ditto, Valentina Varisco, Federica Rigamonti, Alessandra Mutili, Fabiola Atzeni, Alberto Batticciotto and Piercarlo Sarzi-Puttini. L. Sacco University Hospital, Milan, Italy.

Background/Purpose: Interstitial lung disease (RA-ILD) is one of the most serious extrarticular complications of rheumatoid arthritis (RA). Presently, it is not clear which is the best strategy for the detection of RA-ILD. We have previously reported on the feasibility and accuracy of lung ultrasound (LUS) in the detection of RA-ILD (1). Aim of the present study was to assess the performance of LUS in the detection of RA-ILD in clinical practice, and to compare its accuracy with the detection algorithms usually adopted.

Methods: 147 unselected RA patients (114 F and 33 M) were studied. In all patients, LUS was performed as previously described (1) by an expert physician (MC), blinded to clinical and HRCT data, using a standard commercially available US equipment (Esaote MyLabfive) with a 7.5–12 MHz probe. By LUS, RA-ILD was defined by a B-lines score >10. The results of the LUS study were compared to clinical, pulmonary function tests, chest X-ray, and lung CT (HRCT) data, as available from clinical records. Four clinical algorithms (ALG) were identified: ALG 1: presence of dyspnea (NYHA class >2), fever and bibasilar crackles; ALG 2: as ALG 1 + FVC < 80%; ALG 3: as ALG 1 + DLCO < 80%; ALG 4: as ALG 1 + evidence of ILD at chest X-ray. Sensitivity, specificity, and predictive values of LUS and clinical algorithms with reference to HRCT were calculated, and compared by McNemar test.

Results: RA-ILD was detected by LUS in 41/146 (28.1%) patients. Clinical data, FVC, DLCO, X-ray, and CT were available in 146(100%), 63(43%), 61(42%), 102(70%), and 67(46%) cases respectively. LUS showed a significantly higher accuracy in the detection of RA-ILD than clinical algorithms (Table 1). 33/64 (52%) asymptomatic patients, and 31/82 (38%) patients with clinical suspicion of RA-ILD, were not further evaluated by neither PFTs nor by HRCT. Overall, LUS detected unsuspected signs of RA-ILD in 9/146(6%) patients (Fig 1).

Conclusion: LUS is more accurate than usual clinical algorithms in the evaluation of RA-ILD, and allows the detection of a substantial number of unsuspected cases.

Table 1 - Sensitivity, specificity, and predictive power of LUS and clinical algorithms in the detection of RA-ILD. HRCT is the gold standard.

ACR Concurrent Abstract Session
Sjögren’s Syndrome: November 12, 2014; 9:00 AM–10:30 AM

Distinct Serum Protein Signature and Novel Biomarkers of primary Sjögren’s Syndrome Revealed by comprehensive High-Throughput Proteomic Analysis. A yumi Nishikawa1, Katsuya Suzuki2, Yoshiaki Kassai2, Y. yumi Got01, Takahiro Miyazi2, Maiko Takiguchi2, Masaru Takeshita1, Atsuko Murota3, Rimppei Morita3, Akihiko Yoshimura2, and Tsutomu Takeuchi21. Keio University School of Medicine, Tokyo, Japan, 2Takeda Pharmaceutical Company Limited, Kanagawa, Japan, 3Takeda Pharmaceutical Company Limited, Tokyo, Japan, *Department of Medical and Immunology, Keio University School of Medicine, Tokyo, Japan.

Background/Purpose: The EULAR SS Disease Activity Index (ESSDAI) is currently used as an objective evaluation method of clinical disease activity in clinical research into primary Sjögren’s syndrome (pSS). This comprehensive indicator reflects patient signs and symptoms and organ involvement. However, a useful substitute serum biomarker of disease activity has not been established. Although several proteomic investigations of small and large salivary and lachrymal glands have been recently reported, information on serum protein is insufficient. Here, we aimed to reveal a distinct serum protein signature of pSS and identify novel biomarkers of disease activity.

Methods: We studied 90 serum samples from 30 pSS patients, 30 untreated rheumatoid arthritis (RA) patients as non-SS autoimmune disease controls, and 30 healthy control (HC) subjects. 1128 serum proteins, including inflammatory cytokines and chemokines, were quantitatively measured by comprehensive high-throughput proteomics assay using nuclear acid aptamers (SOMAscan Assay; Somalogic Inc, CO, USA). Associations between serum protein concentrations, clinical indicators and laboratory test results were statistically analyzed.

Results: A total of 58 proteins for statistical reasons, 1100 of 1128 proteins in 90 subjects were analyzed. We first screened differentially up- and down-regulated proteins among the three groups, by which 195 proteins, including some overlap (83; pSS vs HC, 124; RA vs HC, 81; pSS vs RA), were statistically extracted (p<0.05 in the t-test and U-test, and fold change ≥ 1.2 or ≤ 0.83). Sixty proteins were up-regulated in pSS compared with HC, including BAPF (pSS patients/healthy control subjects: 9.4-fold), TAL (1.82-fold), VWF (1.57-fold), p2-microglobulin (1.47-fold), while 25 were down-regulated, including Immunoglobulin (lg) D (0.21-fold), CTAP-III (0.79-fold), and GP1% (0.83-fold). Enrichment analysis for characterization of up-regulated genes identified these as cytokines and chemokines including TNF-associated molecules and coagulation factors, indicating a serum protein signature in pSS. Multivariate analysis of these 60 proteins and ESSDAI identified 15 proteins with a statistically positive correlation, including TNF-associated molecules (BAPF, sCD163, TRAIL-R4 and others), LAG-3, p2-microglobulin, and others.

Conclusion: This comprehensive proteomics analysis highlighted a dysregulated immunity and coagulation signature in patients with pSS. Fifteen up-regulated proteins were found to be correlated with disease activity. These proteins are candidate serum biomarkers for use in the clinical prediction of disease activity of pSS.

Lessard1. 1Oklahoma Medical Research Foundation, Oklahoma City, OK, 2Hefner Eye Care and Optical Center, Oklahoma City, OK, 3University of Oklahoma Health Sciences Center, Oklahoma City, OK, 4University of Minnesota, Minneapolis, MN, 5Center for Autoimmune Diseases Research (CREA), Universidad del Rosario, Bogota, Colombia, 6Cedars-Sinaí Medical Center, West Hollywood, CA, 7Hennepin County Medical Center, Minneapolis, MN, 8Cedars-Sinaí Medical Center, Los Angeles, CA, 9US Department of Veterans Affairs Medical Center, Oklahoma City, OK, 10Oklahoma Medical Research Foundation, Oklahoma City, OK.

Background/Purpose: Sjogren’s syndrome (SS) is a common autoimmune disorder characterized by immune-mediated exocrine gland destruction and systemic inflammatory responses that contribute to clinical heterogeneity. Widespread dysregulation of transcribed RNAs in SS, including coding and non-coding elements, has been identified, but the complex regulatory mechanisms governing these responses are poorly understood. We performed an RNA-sequencing (RNA-seq) study that identified over 2,600 differentially expressed (DE) transcripts associated with SS, including 969 long non-coding RNAs (lncRNAs). This study sought to validate, replicate, and functionally characterize one upregulated IncRNA mapped to chromosome 2p25.1, SSINCR1, to better understand its role in SS pathogenesis.

Methods: Whole blood RNA from 27 healthy controls and 57 SS patients was sequenced, and 2,632 statistically significant DE transcripts were identified. Technical validation and replication of SSINCR1 upregulation was assessed by qRT-PCR in an independent set of 36 SS patients and 21 controls. Bioinformatic analyses using GAMMA-seq and the IncRNA database were performed to identify co-expression patterns of SSINCR1 with other coding and non-coding transcripts and to identify candidate protein binding partners. To determine cellular expression patterns of SSINCR1, we employed fluorescence-assisted cell sorting (FACS) staining for 10 distinct immune cell subsets in a healthy control followed by RNA isolation and assessed SSINCR1 expression by qRT-PCR. Statistical comparisons were made using t-tests and Pearson correlations.

Results: RNA-seq showed significant upregulation of SSINCR1 when comparing healthy controls and SS patients (P_value=3.69×10^-5; Fold Change=-2.4). Technical validation by qRT-PCR using the RNA-seq cDNA library confirmed this finding (P=0.0096), and correlation with RNA-seq results was observed (r=0.869). Transcript expression in an independent sample set replicated and confirmed SSINCR1 upregulation (P=0.0183). Co-expression patterns by GAMMA-seq showed T, NK, and dendritic cell activation, development, and proliferation, and assessment of SSINCR1 using IncRNA tor suggested protein binding with cyclin T1 and FIP1L1. FACS analysis showed that SSINCR1 expression levels were highest in the CD3+CD56+ compartment (containing NK cells; relative units [RU]=8.25), followed by CD8+ T cells (RU=3.34), CD56+ NK cells (RU=2.08), CD56hi NK cells (RU=0.83), and CD4+ T cells (RU=0.81). Expression was not detected in CD14+ and CD1c+CD1c+ myeloid DCs, monocytes, B cells, or pDCs.

Conclusion: We have identified, technically validated, and independently replicated the upregulation of a novel SS IncRNA, SSINCR1. We show that transcript expression is highly enriched in CD4+ and CD8+ T cells, NK cells, and NK cells. Ongoing studies are assessing potential protein binding partners and SSINCR1 expression in refined T and NK subsets and in expanded groups of affected and healthy individuals to determine subset-specific DE. This study establishes SSINCR1 as the first IncRNA associated with SS and lays the groundwork for further functional characterization in the pathogenesis of this complex disorder.

Nucleic Acid Sensing Receptors TL7R, RIG-I and MDA5 Collaborate in Driving the Systemic IFN Signature and Amplify the Pathogenic Loop: Potential New Targets for Therapy in Primary Sjögren’s Syndrome. Naomi I. Maria1, Cornelia G. van Helden-Meeuwsen2, Eline C. Steenwijk3, Arne S. J. Ijms4, Wouter Beumer5, Zana Brkic5, Virgil A. Dalm4, Paul L. van Dael6, Pi M. Martin van Hagen6, Peter J. van der Spek6, Hemmo A. Drexhage6, and Marjan A. Versnel7. 1Erasmus Medical Center, Immunology, Rotterdam, Netherlands, 2Erasmus Medical Center, Bioinformatics, Rotterdam, Netherlands.

Background/ Purpose: Primary Sjögren’s syndrome (pSS) is a systemic autoimmune disease characterized by autoantibodies targeting RNA-associated antigens, anti-SSA/SSB. The IFN signature is present in over 50% of pSS patients, and is associated with higher disease-activity and autoimmune presence. Endosomal Toll-like receptor-like, RLR7 and TL9, are crucial for both the generation of auto-antibodies by B-cells and immune-complex-mediated production by plasmacytoid dendritic cells (pDCs) in autoimmunity. Recently opposing effects were described for RLR7 and TL9 in murine lupus-molds, where TL9-deletion limited autoimmunity and TL9-deletion paradoxically exacerbated disease. Interestingly, we recently found the TL9-pathway upregulated in IFN-positive pDCs of pSS patients, whereas TL9 was not. Here we set out to further investigate this imbalanced endosomal TL9-signaling in IFN-driven pSS.

Methods: Blood samples were obtained from 58 healthy controls (HC) and 58 pSS patients, diagnosed according to the 2002 American-European criteria, and stratified according to their IFN signature. Fluorescence-activated cell sorting was used to isolate CD123+BDCA4+ pDCs, CD14+ monocytes, CD3+ T-cells and CD19+ B-cells >98% purity, from peripheral blood mononuclear cells (PBMCs). Genome-wide Microarray analysis conducted on sorted pDCs and monocytes revealed increased expression of cytoplasmic and endosomal pattern recognition receptors: TLR7, retinoic acid inducible gene-1 (RIG-I/DDX58), melanoma differentiation associated gene 5 (MAF-5/IFIH1), and further downstream MYD88-dependent signaling, confined to IFN-positive patients. mRNA expression of the resulting differentially expressed genes (DEGs), as assessed by Ingenuity pathway analysis (IPA), was validated in sorted cell-suspensions and whole blood (Paxgene) using real-time quantitative PCR. To further clarify the possible TL9-driven activation of the IFN signature, PBMCs of HC were stimulated in vitro with imiquimod, a TLR7 agonist, and inhibited with the TLR7 antagonist IRS661. RNA-sensing receptors RIG-I and MDA-5 (p<0.001) were specifically downregulated, as assessed by Ingenuity pathway analysis (IPA), was validated in sorted cell-suspensions and whole blood (Paxgene) using real-time quantitative PCR. To further clarify the possible TL9-driven activation of the IFN signature, PBMCs of HC were stimulated in vitro with imiquimod, a TLR7 agonist, and inhibited with the TLR7 antagonist IRS661.

Results: Confirming our microarray results, we found an upregulation of TLR7 (p<0.05), but not TL9, in IFN positive pDCs, monocytes, B-cells and in whole blood (p<0.0001) as well as further downstream MYD88, RAS2 D2 and IRF7 (p<0.001). We also observed the upregulation of intracellular RNA-sensing receptors RIG-1 and MDA-5 (p<0.01), recently described to collectively initiate effective IFN signaling. This widespread upregulation of TLR7 and its downstream signaling pathway is confined to IFN-positive pSS patients. In vitro studies with HC-PBMCs reveal that triggering of the TL9-pathway by Imiquimod causes further upregulation of the other RNA-sensing receptors RIG-1 and MDA-5, inflammatory cytokines, IFN-inducible genes and also BAFF. Specific TLR7-inhibition subsequently showed a dose-dependent decrease.

Conclusion: Taken together, these RNA-sensing receptors — TLR7, RIG-I and MDA-5 — seem to collaborate in amplifying the pathogenic IFN-driven loop in pSS. A better understanding of this unrestrained and potentially auto-reactive loop reveals novel targets for therapeutic interventions in pSS.

**Genome-Wide DNA Methylation Analysis of CD19+ B Cells in Primary Sjögren’s Syndrome.** Gunnel Nordmark1, Juliana Irgemgen-Kreuz2, Jonas Carlson Aalmof2, Jessica Nordlund1, Roald Omdal1, Katriine H. Norheim2, Maija-Leena Etoransa1, Lars Rönnblom2 and Johanna K. Sandling1.1Rheumatology, Department of Medical Sciences, Uppsala University, Uppsala, Sweden, 2Molecular Medicine and Science for Life Laboratory, Department of Medical Sciences, Uppsala University, Uppsala, Sweden. 

**Background/Purpose:** Increasing evidence suggests an epigenetic contribution to the pathogenesis of autoimmune diseases, including primary Sjögren’s Syndrome (pSS) (1). A genome-wide DNA methylation study in T cells from patients with pSS and controls identified a large number of differentially methylated genes (2). B cells play an important role in pSS with production of autoantibodies and the potential development of B cell lymphomas. The aim of this study was to investigate DNA methylation profiles in purified CD19+ B cells from patients with pSS and healthy controls.

**Methods:** Seventeen female patients with pSS, mean age 53.2 years and 28 healthy blood donors, 11 females/17 males, mean age 46.7 years were included. All patients fulfilled the AECG criteria for pSS, 94.1% were anti-SSA and/or -SSB positive and none of the patients had lymphoma. DNA was prepared from CD19+ B cells positively selected from fresh blood samples. Genome-wide DNA methylation profiles were generated on the Illumina HumanMethylation450 BeadChip array. After quality control and normalization, 383,258 CpG sites remained. A threshold of 10% difference between cases and controls in average methylation level per CpG site was applied. Age and sex were included as covariates and a Bonferroni corrected p-value of <1·10^-7 was considered significant.

**Results:** We identified 482 differentially methylated CpG sites, 91 hypomethylated annotated to 63 genes and 391 hypermethylated annotated to 316 genes. Pathway analysis of genes with hypomethylated sites showed over-representation in Interferon signalling genes, and for genes with hypermethylated sites Syndecan-1-mediated signalling events and the EGF receptor signalling pathway. Disease association of genes with differentially methylated sites showed enrichment for genes implicated in cancer, viral infections and B cell and follicular lymphomas. The most distinct difference in average methylation was observed in the interferon-induced gene IFI44L with 31% decreased methylation in pSS CD19+ B cells compared to control B cells.

**Conclusion:** Our results demonstrate that DNA methylation is altered in CD19+ B cells from patients with pSS, which underscores the importance of these cells in the pathogenesis of the disease. The significance of genes in the interferon system is highlighted and the enrichment of genes involved in B cell lymphoma is intriguing and warrants further investigation.

2981

**Prognostic Value of the Complex P2X7 Receptor-Inflammasome in Patients with Primary Sjögren’s Syndrome at Lymphoma Risk.** Chiara Baldini1, Eleonora Santini2, Chiara Rossi3, Francesca Sernisci1, Daniela Martini1, Alessia Gallo3, Valentina Donati3, Nicoletta Luciano3, Francesco Ferro4, Illias Alevizos3, Anna Solini2 and Stefano Bombardieri3.1Rheumatology Unit, Pisa, Italy, 2Rheumatology Unit, University of Pisa, Pisa, Italy, 3NIDCR, Bethesda, M.D.

**Background/Purpose:** Pro-inflammatory P2X7 receptor has been recently implicated in the pathogenesis of primary Sjögren’s syndrome (pSS), suggesting that it may be involved in the initiation and amplification of the innate immune response in salivary glands. In particular, previous studies have shown that the expression of P2X7 receptor in minor salivary glands was significantly higher in patients with positive anti-Ro-SSA and that it correlated with the minor salivary gland biopsy focus score. To date, however, no data are available on the role of the complex P2X7 receptor-inflammasome in the prognostic stratification of patients with pSS, specifically concerning their risk for lymphoma. The aim of this study was, therefore, to explore any eventual association or correlation between P2X7 mRNA levels in pSS minor salivary glands and in blood peripheral lymphocytes and traditional histological and serological risk factors for lymphoma in pSS.

**Methods:** Consecutive, unselected patients with a diagnosis of pSS made according to the AECG 2002 were enrolled in this study. All subjects had a standardized evaluation for pSS which included oral and ophthalmologic examinations, laboratory testing and a rheumatologic evaluation. Mononuclear cells were isolated from fresh blood by density gradient centrifugation. Total RNA was extracted from the frozen salivary gland tissue and from the frozen pellet of lymphocytes and expression of the P2X7 7R mRNA was determined by real-time PCR. Minor salivary gland biopsies were re-evaluated by light microscopy in order to identify GC-like structures. For statistical comparisons, non parametric Mann-Whitney test and Spearman’s rank correlation coefficient were employed.

**Results:** Twenty pSS subjects were enrolled in the study. At diagnosis, 20% of pSS patients had GC-like structures in their salivary glands. P2X7 mRNA expression was significantly higher in the salivary glands of pSS with GC-like structures than in those without GC-like structures and correlated significantly with minor salivary gland focus score (r = 0.688, p = 0.000), beta-2 microglobulin levels (r = 0.538, p = 0.02) and IgG levels (r = 0.452, p = 0.02). Moreover, P2X7 7R mRNA expression levels were significantly higher in patients with clinically evident major salivary glands enlargement and/or disease specific parenchyma dyshomogenization documented by salivary gland ultrasound. No significant correlations were found between P2X7 7R expression in peripheral lymphocytes and all the histological and laboratory risk factors for lymphoma examined in the study.

**Conclusion:** The results of this proof of concept study reinforce the potential involvement of the salivary P2X7 7R in pSS chronic salivary inflammation which have consistently been associated with an increased risk of malignant lymphomas. Further investigation are mandatory to clarify whether salivary P2X7 7R expression might be useful to identify pSS patients at lymphoma risk.

2982

**Identification of Whole Blood Gene Expression Signature in Primary Sjögren’s Syndrome Associated Lymphoma.** Shereen Al-Ali1, Simon Cockell1, Andrew Skelton1, Katherine James1, Jessica Tarn2, David Young3, Bridget Griffiths4, Simon Bowman5, James Locke6 and Wan-Fai Ng7.1University of Basrah, Basrah, Iraq, 2Newcastle University, Newcastle upon Tyne, United Kingdom, 3Newcastle University, Newcastle Upon Tyne, United Kingdom, 4Freeman Hospital, Newcastle Upon Tyne, United Kingdom, 5University Hospital Birmingham, Birmingham, United Kingdom.

**Background/Purpose:** Primary Sjögren’s syndrome (pSS) is associated with a substantially increased risk of lymphoma development. The aim of our study is to identify a whole blood gene expression signature of pSS-associated lymphoma and to explore the potential biological significance of such signature using pathway and network analysis.

**Methods:** Whole blood RNA samples (n=144) from pSS patients and healthy controls taken part in the UK primary Sjögren’s syndrome registry (UKPSSR). All patients fulfilled the AECG criteria and were stratified into five clinical subsets (pSS = 61, pSS with lymphoma = 16, pSS with other cancers = 21, pSS with paraproteinemia = 23 and healthy controls = 23).

**Results:** Distinct gene expression profiles and similar differentially expressed genes were observed when comparing each clinical subset with healthy controls. Comparison between the “Lymphoma” group and those without lymphoma revealed 25 upregulated genes and 43 downregulated genes. When compared with pSS patients with other cancers, only one gene was differentially expressed and it was
Fatty lesions of the bone marrow in the axial skeleton (sacroiliac joints - SIJ, and spine) on magnetic resonance imaging (MRI) are considered nowadays as earliest post-inflammatory changes preceding new bone formation in axial spondyloarthritides (axSpA). It has been shown in several trials with tumour necrosis factor (TNF) α inhibitors that resolution of inflammation under anti-TNF therapy is associated with an increase of a fatty lesion score. This raised concerns that TNF blockers might therefore promote the process of new bone formation in axSpA. The aim of the current analysis was to investigate the difference in fatty lesions formation rates in patients treated with the TNF inhibitor infliximab (IFX) added to naproxen (NPX) as compared to NPX alone given over 28 weeks in patients with early axSpA.

Methods: Part I of the INFAST study was a double-blind, randomized controlled trial of IFX in biologic-naive patients 18–48 years of age with early (<3 years symptom duration), active axSpA with signs of active sacroiliac on MRI. A total of 158 patients were randomized (2:1) to receive 28 weeks of treatment with either intravenous IFX 5 mg/kg (weeks 2, 6, 12, 18, and 24) + NPX 1000 mg/d (n=106) or intravenous PBO+NPX 1000 mg/d (n=52). MRI’s of the SIJ and of the spine were performed at baseline and week 28 and were scored according to the Berlin scoring system for active inflammation and for fatty lesions, including a detailed fatty degeneration score for the SIJ by a reader who was blinded for clinical data including treatment allocation.

Results: Complete MRI sets (baseline and week 28, both STIR and T1-weighted sequences) were available in 147 patients for the spine (n=99 IFX + NPX, n=48 NPX alone) and in 143 patients for the SIJ (n=97 IFX + NPX, n=46 NPX alone). At baseline there were no meaningful differences between treatment group neither in osteitis nor in fatty lesion scores. In both treatment groups there was a significant reduction of inflammation in the spine and in the SIJ at week 28 as compared to baseline. In table, which was however more prominent in the combined treatment group since after 28 weeks patients in the IFX + NPX group had significantly lower osteitis scores in the SIJ (p<0.001) and in the spine (p<0.001). Similarly, in both groups there was a significant and comparable increase in the fatty lesion score (table) in the spine and in the SIJ at week 28 as compared to baseline, but no statistically significant difference between treatment groups was observed in the fatty lesion status score at week 28.

Conclusion: Effective anti-inflammatory treatment of axSpA in this study was associated with an increase in the fatty lesion score in the SIJ and in the spine that was independent of the treatment arm. The results suggest that fatty lesion formation after resolution of inflammation is possibly a universal pathogenetic mechanism in axSpA and not a direct effect of anti-TNF therapy.

Table 1. Changes in MRI scores over 28 weeks in patients with active axSpA in the INFAST study.

*SWilcoxon Test, Week 28 vs Baseline
healthy controls were screened against ten 14-3-3 with inflammation and have diagnostic and prognostic properties. Were generated in AS and which specific autoantibody might be associated groove. We aimed to determine whether autoantibodies to the native protein inflammatory cascades that result in expression of inflammatory factors and 51 (44%) received TNF blocker therapy. Mean (SD) baseline mSASSS assessed by CRP and MRI of the sacroiliac joint (SIJ) and spine, which was performed by two central readers and an adjudicator using the modified Stoke AS Spine Score (mSASSS). Patients had mean age of 39.7 years, 73% male, mean symptom duration 16.9 years, and S1 (44%) received TNF blocker therapy. Mean (SD) baseline mSASSS was 13.6 (17.6), mean change in mSASSS was 1.8 (2.7), and 52.5% had mSASSS change > 0. Mann-Whitney U test was used to determine group differences and ROC analysis (AUC) was used to assess diagnostic utility. Potential associations were assessed by Pearson correlation. Multivariate regression analyses were used to examine associations significant in univariate analyses.

Results: Discrimination by AUC ranged from 0.81–0.89 for all 10 autoantibodies (p<0.0001 for all). For example, median (SD) expression of the Pan-3 14-3-3 autoantibody was significantly higher in SpA than in healthy controls (838 U/ml (605–1287) vs. 456 U/ml (346–566), p=0.0001) and area under the ROC curve was 0.86, 95%CI (0.82–0.91). A cut-off of 803 U/ml delivered 95% specificity and 53% sensitivity (LR + = 11.2, LR - = 0.5). For inflammation parameters, Pan-1 and Pan-5 correlated significantly with CRP (r=0.23, p=0.02; r=0.27, p=0.005) and Pan-1 correlated with SPARCC SIJ MRI score (r=0.21, p=0.04). For radiographic progression measured by change in mSASSS, significant correlations were observed with all 10 Pan specificities, notably, Pan-2 (r=0.39, p<0.0001), Pan-3 (r=0.34, p=0.0004), and Pan-10 (r=0.35, p<0.0003). Independent predictors of MRI inflammation were sex (p=0.006) and Pan 1 autoantibody (p=0.008) (adjusted for age, sex, symptom duration, CRP). Controlling for baseline mSASSS CRP, age, sex, symptom duration, and treatment, Pan antibodies were the only significant predictors of the change in mSASSS at 2 years in multivariate regression analysis. Pan composite score (p=0.001), Pan-1 (p=0.008), Pan-2 (p=0.001), Pan-3 (0.005), Pan-10 (p=0.0004).

Conclusion: 14-3-3 autoantibodies are novel serum markers that are differentially expressed in AS versus healthy controls. They are significantly associated with MRI inflammation and baseline expression of several autoantibody specificities predicts radiographic progression.

Fat Metaplasia on MRI of the Sacroiliac Joints Is a Lead Indicator of Radiographic Progression in the Spine of Patients with Ankylosing Spondylitis. WP Maksymowych1, Stephanie Wichuk1, RG Lambert2, MA Reed Murdoch1 and ANTHONY MAROTTA2. 1University of Alberta, Edmonton, AB, 2Molding, University of Alberta, Edmonton, AB.

Background/Purpose: Fat metaplasia in the SIJ on MRI is an early feature of sacroiliitis and occurs both in subchondral bone marrow and also in the excavated area caused by erosion, when it is called backfill. Recent data has shown that these lesions are key intermediaries in the development of SIJ ankylosis. We aimed to test the hypothesis that these lesions may also be lead indicators of new bone formation in the spine of patients with axial SpA. This could provide an important target for therapeutic intervention.

Methods: Bone marrow fat metaplasia and backfill were scored using the SPARCC MRI SIJ structural score (SSS) by two readers and an adjudicator using pre-specified rules for adjudication. 137 pairs of MRI scans blinded to time point (baseline, 2 years) were assessed from a prospective cohort of AS patients (mean age 40.5 years, mean symptom duration 16.9 years, 53% on anti-TNF) followed for mean 2.3 years. Two readers and an adjudicator independently scored pairs of radiographs (baseline, 2 years) from the same patients using the mSASSS. Radiographic progression was compared in patients with and without positive SIJ MRI for fat metaplasia (SSS score ≥ 2 or <2) and the degree of SIJ fat metaplasia at baseline (absolute SSS score) was compared in patients with and without radiographic progression (mSASSS > 0 or =0) using Mann-Whitney and cumulative probability. Multivariate regression analyses included variables significant in univariate analyses (age, sex, symptom duration, CRP, baseline mSASSS) and treatment.

Results: Radiographic progression was significantly greater in those with positive SIJ fat metaplasia (p=0.015) (figure), and especially in patients who only received non-biologic therapy (p=0.023). Baseline SSS SIJ fat metaplasia scores were significantly higher in those who developed radiographic progression compared to those without (1.58 vs 0.65, p=0.008). Both positive SIJ MRI for fat metaplasia and the degree of fat metaplasia were significantly associated with radiographic progression in multivariate analyses (β=0.38 (p=0.005) and β=0.06 (p=0.0001) respectively). SSS score for backfill was also significantly associated with radiographic progression in multivariate analysis (β=0.04 (p=0.199)).

2985

Autoantibodies to 14-3-3γ Are Novel Biomarkers Associated with Inflammation and Radiographic Progression in Ankylosing Spondylitis. WP Maksymowych1, Stephanie Wichuk1, RG Lambert1, M. Reed Murdoch1 and Anthony Marotta2. 1University of Alberta, Edmonton, AB, 2Augurex Life Sciences Corp, North Vancouver, BC.

Background/Purpose: 14-3-3γ is a ubiquitous intracellular chaperone protein that is expressed extracellularly in rheumatoid arthritis and mediates inflammatory cascades that result in expression of inflammatory factors and metalloproteinas. An autoantibody response (AAb) is elicited to a range of epitopes on the native protein both within and outside the ligand-binding groove. We aimed to determine whether autoantibodies to the native protein were generated in AS and which specific autoantibody might be associated with inflammation and have diagnostic and prognostic properties.

Methods: Sera from 116 patients with AS followed prospectively and 106 healthy controls were screened against ten 14-3-3γ peptides (Pan 1–10) using an electrochemiluminescent multiplex assay platform. Inflammation was assessed by CRP and MRI of the sacroiliac joint (SIJ) and spine, which was performed by two central readers and an adjudicator using the Spondyloarthitis Research Consortium of Canada (SPARCC) score. Radiographic progression over 2 years was assessed by two central readers and an adjudicator using the modified Stoke AS Spine Score (mSASSS). Patients had mean age of 39.7 years, 73% male, mean symptom duration 16.9 years, and S1 (44%) received TNF blocker therapy. Mean (SD) baseline mSASSS was 13.6 (17.6), mean change in mSASSS was 1.8 (2.7), and 52.5% had mSASSS change > 0. Mann-Whitney U test was used to determine group differences and ROC analysis (AUC) was used to assess diagnostic utility. Potential associations were assessed by Pearson correlation. Multivariate regression analyses were used to examine associations significant in univariate analyses.

Results: Discrimination by AUC ranged from 0.81–0.89 for all 10 autoantibodies (p<0.0001 for all). For example, median (SD) expression of the Pan-1 14-3-3γ autoantibody was significantly higher in SpA than in healthy controls (838 U/ml (605–1287) vs. 456 U/ml (346–566), p=0.0001) and area under the ROC curve was 0.86, 95%CI (0.82–0.91). A cut-off of 803 U/ml delivered 95% specificity and 53% sensitivity (LR + = 11.2, LR - = 0.5). For inflammation parameters, Pan-1 and Pan-5 correlated significantly with CRP
Conclusion: The appearance of fat metaplasia in SIJ subchondral bone marrow and/or at sites of erosion in the SIJ may identify AS patients at increased risk of radiographic progression in the spine.

Value of Color Doppler Ultrasound Assessment of Sacroiliac Joints in Patients with Inflammatory Chronic Low Back Pain. Maximiliano Bravo1, Leandro Ferreyra Garrott2, David A. Navarta3, Emmanuel Bertiller4, Ricardo Garcia-M Onaco5, Santiago Ruta6, Javier Rosa6 and Enrique Soriano1.

1Rheumatology Unit, Internal Medical Services, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, 2Radiology and Imagingology Department, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, 3Rheumatology Unit, Internal Medicine Service, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina.

Background/Purpose: The utility of ultrasound in the evaluation of sacroilitis has not been extensively studied yet. To evaluate the diagnostic value of color Doppler ultrasound (US) for the detection of sacroiliac (SI) active inflammatory lesions in patients with inflammatory chronic low back pain (LBP).

Methods: Consecutive patients older than 18 years, with chronic inflammatory low back pain, defined as LBP with more than 3 months of continuous duration, of insidious onset, with improvement with exercise, no improvement with rest, and pain at night (with improvement upon getting up), without a definitive diagnosis (patients at risk of having undetected spondyloarthritides (SpA)), were included. Patients with Ankylosing spondylitis (AS) according to modified New York criteria, were included as control group.

Clinical assessment included BASDAI, BASFI, and HAQ. Ultrasound evaluation was performed by a blinded rheumatologist experienced in this technique with a My lab 70 machine (Esaote) with a multi-frequency convex array transducer (1-8 MHz). Standardized scanning method was used to investigate increased local perfusion with color Doppler US. When color Doppler signal was found in or around the SI joints, spectral Doppler was used and the resistive index (RI) was measured. Color Doppler US sacroiliac joints was defined as a positive color Doppler signal with a RI < 0.75 at any of the SI joints.

The following sequences were used on the MRI assessment: T1-weighted spin echo (SE) and short-tau inversion recovery (STIR). MRI sacroiliac joints was defined according to ASAS definition of active sacroiliac inflammatory lesions.

Sensitivity, specificity, positive and negative predictive values for the diagnosis of sacroiliitis by color Doppler US features were calculated, using MRI as the gold standard.

Results: Forty-four patients were included. Twenty-four (54%) were males. Mean age was: 40 years (SD: 11 yrs). Median disease duration was 2 years (IQR: 0.5–10 yrs). Mean BASDAI was 4.8 (SD: 2.4), mean BASFI: 3.6 (SD: 2.7), and mean HAQ was 0.6 (SD: 0.5). Ten patients had AS. Among all patients observed values were: sensitivity 59 % (95% CI: 42–75%), specificity: 94% (95% CI: 83–99.6%). Positive predictive value (PPV) was 87% (95% CI: 77–100%) and negative predictive value (NPV) was: 83% (95% CI: 72–94%). Among AS patients observed values were: sensitivity 83% (95% CI: 60–99), PPV: 75% (95% CI: 48–100) and NPV: 83% (95% CI: 60–99%) and among inflammatory LBP patients diagnostic test values were: sensitivity 59 % (95% CI:42–75%), specificity: 94% (95% CI:86–100%), PPV: 91% (95% CI:81–100) and NPV: 70% (95% CI: 54–89%).

Conclusion: color Doppler US seems to be a practical and useful tool for the diagnosis of active sacroiliitis. Larger studies would be needed to confirm these results.

2988

1Department of Rheumatology Ghent University Hospital, Ghent, Belgium, 2Institute of Immunology University of Muenster, Muenster, Germany, 3Department of Pathology Ghent University Hospital, Ghent, Belgium, 4University Children’s Hospital Muenster, Muenster, Germany.

Background/Purpose: Microscopic gut inflammation is present in about 50% of spondyloarthritides (SpA) patients. Two types can be distinguished: an acute type resembling infectious enterocolitis, and a chronic type similar to early Crohn’s disease. Although subclinical, microscopic gut inflammation appears to be a prognostic factor in SpA, linked with more extensive disease and a less favorable outcome. At this moment, however, reliable biomarkers are missing. The calgranulins S100A8/S100A9 and S100A12 are very sensitive markers of innate immune activation. They are released from monocytes and granulocytes in the early phase of the immune response and exert important pro-inflammatory effects via Toll-like receptor 4 dependent mechanisms. Calgranulins can be measured in serum and stool. Moreover, the S100A8/S100A9 heterodimer, also called calprotectin, has been established for a long time as a fecal marker of disease activity in inflammatory bowel disease. Our aim was to assess whether calgranulins can be used as biomarkers for microscopic gut inflammation in SpA.

Methods: Serum levels of calgranulins were measured in 103 newly diagnosed SpA patients and 24 healthy controls. Ninety seven SpA patients underwent an ileocolonoscopy to assess the presence of microscopic gut inflammation. Ileal and colonic biopsies were histologically scored and subsequently immuno-stained for S100A8 and S100A9.

Results and Conclusion: Serum levels of S100A8/S100A9 and S100A12 were significantly higher in SpA patients versus healthy controls (p = 0.035 and p = 0.024). Levels correlated moderately with CRP, but not with ASDAS, BASDAI or swollen joint count. SpA patients with the acute type of microscopic gut inflammation (N = 17) had significantly higher calgranulin levels compared to those with normal gut histology (N = 56) (p = 0.021 for S100A8/S100A9 and p = 0.05 for S100A12). Furthermore, immunohistology showed high staining of S100A8 and S100A9 on acutely inflamed gut biopsies, compared to absent/minimal staining on normal biopsies. Chronically inflamed biopsies (N = 24) stained positive only when they had high inflammatory activity (in ~ 50% of cases). Importantly, NSAID intake had neither influence on immunohistology stainings nor on serum levels of calgranulins. To conclude, we found that calgranulin levels, both systemically and locally, marked the presence of acute microscopic gut inflammation in SpA. These results illustrate their high sensitivity as they reflected inflammation present only on a subclinical level. Therefore we anticipate that they may be of particular value in detecting (or excluding) latent (systemic) disease.

ACR Concurrent Abstract Session
Systemic Lupus Erythematosus - Clinical Aspects and Treatment: Central Nervous System and Other Clinical Aspects

Wednesday, November 19, 2014, 9:00 AM–10:30 AM

2989

Lupus Impact Tracker Is Responsive to Changes in Disease Activity in Lupus. David Giangreco1, Hevè Devillers2, Nandreer Amanappedry3, Joel A. Block1 and M enakshi jolly3.

1Department of Rheumatology Ghent University Hospital, Ghent, Belgium, 2Department of Rheumatology Ghent University Hospital, Ghent, Belgium, 3Department of Internal Medicine and Systemic diseases, Dijon, France.

Background/Purpose: Patient reported outcomes (PRO) are important to understand, educate, manage and follow patients with systemic lupus erythematosus (SLE). Lupus Impact Tracker (LIT) is a ten-item tool developed to facilitate patient-physician communication. Herein, we present its responsiveness to physician and patient assessed changes in disease status from data obtained during routine SLE patient care visits.

Disclosure: M. Bravo, UCB, 2; L. Ferreyra Garrott, UCB, 2; D. A. Navarta, UCB, 2; E. Bertiller, UCB, 2; R. García-M Onaco, UCB, 2; S. Ruta, UCB, 2; J. Rosa, UCB, 2; E. Soriano, UCB, 2.
Methods: Longitudinal data on LupusPRO, physician assessed disease activity assessment, and patient reported changes in SLE health status was collected during 182 SLE patient routine clinical visits. LIT score was derived from PRO data. Disease activity assessments used as anchors for testing responsiveness were the SLEDAI physician global assessment (PGA), Total SELENA-SLEDAI score, SELENA-Flare Index (SFI), and Patient reported changes in SLE health status. Cut-offs used to determine change in disease activity were as follows: PGA (change of 0,3), Total SELENA-SLEDAI (change of 4), SFI (remitting of 4), and Flaring) and Patient reported changed in SLE health status (7 to 7). For patient reported change in SLE health status, we categorized −2 to 2 as unchanged, −3 to −7 as worsening and 3 to 7 as improvement. Mixed model regression analysis was used to compare changes in LIT against disease activity and patient reported changes in SLE health status anchors.

Results: There were 658 visit data available for 182 SLE patients. Consecutive visits were 2-5 months apart with a median number of visits per patient of 7. PGA was available for 630 visits; Total SLEDAI was available for 249 visits; SFI was available for 610 visits; Patient reported change in SLE health status was available for 449 visits. Mean (SD) age and SLE-SELENA-SLEDAI were 43.3 (13.2) years and 6.4 (7.3), respectively. PGA changed significantly for 269 visit data (increased in 125, decreased in 144) while 361 visit data had unchanged PGA. Total SELENA-SLEDAI changed significantly among 66 visits (29 increased, 37 decreased) and remained stable among 183 visits. Significant changes in SFI were observed in 194 visit data (80 remitting, 69 flaring) while 461 visit data was unchanged. Patient reported change in SLE health status changed significantly for 221 (150 improved, 71 worsened) and remained stable for 228 visits. LIT scores responded significantly and in the appropriate direction for changes in PGA (p<0.05), Total SLEDAI (p<0.001), and SFI (p<0.05) and patient reported changes in SLE health status (p=0.001).

Conclusion: LIT is responsive to physician- and patient-assessed changes in disease status in SLE. In addition to being used in clinical trials, LIT is an effective tool that may be used by patients and physicians in facilitating communication and tracking disease impact in SLE.

2990

Background/Purpose: Posterior reversible encephalopathy syndrome (PRES) is a well-known but rare complication in systemic lupus erythematosus (SLE) patients (<1%). However, current epidemiologic data is quite scant. The aim of the present study was to describe potentially unrecognized risk factors for PRES.

Methods: We performed a single-center retrospective case-control study in a tertiary care center in Mexico City between 1999 and 2014. We included 48 patients (cases) with SLE diagnosis (≥4 ACR criteria) who presented with reversible neurological manifestations (seizures, visual abnormalities, acute confusional state, among others) associated with changes by magnetic resonance (MRI) (iso or hypointensity in T1 and hyperintensity in T2/FLAIR). Controls (n=96) were patients with SLE without evidence of PRES that were hospitalized during the same period as cases (≥3 months) and matched by gender. Association between variables was calculated by χ2 test and OR (95% CI). Multivariate analysis was performed by logistic regression.

Results: SLE patients with PRES were younger (27.9±1.05 vs 36.2±3.16 years, p<0.001). Ninety percent of the cases occurred in women. PRES occurred in 28/48 patients (40%) after 24 hours of admission (2-30 days). The vast majority (80.2%) of cases presented with seizures, and up to 18% showed “atypical” MRI images. Decrease or resolution of MRI images in the first 12 weeks after the event occurred in 88.8% of cases. Variables associated with the development of PRES, three months prior to hospitalization and at the time of the event are summarized in Table 1. A multivariate analysis, hypertension at admission (OR 16.3, 95% CI 4.03-65.85, p<0.001) and low C3 levels (OR 0.38, 95% CI 0.14-0.98, p=0.039) were independent risk factors for the development of PRES in SLE. Length of hospital stay was similar between groups (17.2±2.07 vs 14.60±1.11 days, p=0.26) and none of the cases died during hospitalization.

Conclusion: Our data is in agreement with prior studies that link end-stage renal disease, hypertension and high SLEDAI scores to the development of PRES in SLE. Furthermore, we found that persistent lymphopenia is a novel independent risk factor for PRES in SLE, which could be related to endothelial dysfunction in these patients.

Anti-Ribosomal P Antibody Is a Key Autoantibody Associated with Complications of NP-SLE with High Levels of CSF IL-8. Hidenagako Kawasumi1, Takahisa Gono1, Yasushi Kawaguchi1, Yasushi Kasumata2, Hisae Ichida1, Aiko Tochimoto1, Masaomi Hanaka1, Yuko Okamoto2, Sayuri Katoaka1 and Hisashi Yamanaka2. 1Tokyo Women’s Medical University, Tokyo, Japan, 2Institute of Rheumatology, Tokyo Women’s Medical University, Tokyo, Japan.

Background/ Purpose: Complications of neuropsychiatric systemic lupus erythematosus (NP-SLE) are associated with the morbidity and mortality of patients with SLE. Although the detailed pathophysiology of NP-SLE remains unknown, complements, autoantibodies, and cytokines are involved in the inflammation of the central nervous system (CNS) or the peripheral nervous system (PNS) in SLE. Previous studies have demonstrated that anti-phospholipid (PL), anti-ribosomal P, anti-N-methyl-D-aspartate receptor subunit 2 (NR2), and anti-U1-RNP antibodies are associated with the development of NP-SLE. In addition, cerebrospinal fluid (CSF) proinflammatory cytokines, such as IL-6, are increased in NP-SLE. In this study, we evaluated the associations between several serum autoantibodies and CSF proinflammatory cytokines in NP-SLE.

Methods: In the present study, seventy patients with SLE who had been admitted to our hospital from 2001 to 2013 were enrolled. SLE was diagnosed according to the 1997 ACR revised criteria for the classification of SLE. Disease activity was measured using the SLE disease activity index 2000 (SLEDAI-2k). NP-SLE manifestations were classified according to the 1999 ACR nomenclature and case definitions for NP-SLE syndromes. Serum and CSF samples were obtained from all enrolled patients with SLE. We measured serum autoantibodies, including anti-PL, anti-ribosomal P, anti-NR2, anti-U1-RNP and anti-Sm antibodies, and CSF cytokines (IL-6, IL-8, and IFN-α).

Results: Of the 70 patients with SLE, all patients were female, and their median age was 32 years. The median score on the SLEDAI-2k was 12. NP-SLE was diagnosed in 24 patients. Serum anti-PL, anti-ribosomal P, anti-NR2, anti-U1-RNP, and anti-Sm antibodies were detected in 15, 23, 23, 24, and 13 patients, respectively. The CSF levels of IL-8 were significantly higher in the NP-SLE subset compared with the non-NP-SLE subset (p<0.05). There were no significant differences in the CSF levels of IL-6, IFN-α, total protein, or IgG index between the two subsets. High levels of CSF IL-8 (>30 pg/ml) were significantly (p<0.001) associated with the complications of NP-SLE. No patient was diagnosed with NP-SLE when the CSF levels of IL-8 were less than 30 pg/ml. To identify the specific autoantibodies associated with high levels of CSF IL-8, a multivariate analysis was conducted. Anti-ribosomal P was the most significant autoantibody involved in the high levels of CSF IL-8.
Conclusion: High levels of CSF IL-8 are associated with the complications of NP-SLE. Anti-ribosomal P is a key autoantibody associated with NP-SLE with high levels of CSF IL-8.

Usefulness of Diagnostic Biomarker for Neuropsychiatric Systemic Lupus Erythematosus By Anti-Microtubule Associated Protein 2 Antibody in Cerebrospinal Fluid. Yusuke Yamada, Department of Internal Medicine and Rheumatology, Juntendo University Faculty of Medicine, Tokyo, Japan.

Background/Purpose: Microtubule associated protein-2 (MAP-2) is found exclusively in nerve cells. MAP-2 has been shown to stabilize microtubules by binding to the outer surface and participate in determining the structure of nerve cells. Interestingly, a previous report has shown that an autoantibody against MAP-2 has been reported to be found in sera with SLE patients especially having neuropsychiatric manifestations. However, there are no additional reports concerning anti-MAP-2 antibody. NPSLE involves a wide range of focal and diffuse central and peripheral nervous system disorders. The diagnosis of NPSLE is often clinically difficult because discrimination of secondary causes such as infection, medication side-effects, and metabolic abnormalities was required. The diagnostic inference of NPSLE can be made only after these secondary causes have been excluded. There is no one single diagnostic tool specific to NPSLE so far. Multiple diagnostic examinations such as IL-6 measurement in cerebrospinal fluid or Magnetic Resonance Imaging (MRI) have been used for diagnosis with NPSLE. However, the findings from these examinations are not specific for NPSLE. Therefore, novel diagnostic biomarkers have been expected to be established. Herein, we conducted this study to clarify that anti-MAP-2 antibody in cerebrospinal fluid can be used for a diagnostic biomarker of NPSLE.

Methods: Anti-MAP-2 antibody, anti-ribosomal P antibody, and IL-6 was measured by ELISA in cerebrospinal fluid from NPSLE patients (n=24) or non NPSLE controls (n=18). The diagnosis with NPSLE was made by the nomenclature system proposed by American College of Rheumatology (ACR, 1999). Non NPSLE controls consisted of SLE patients with CNS disorders caused by the secondary causes such as steroid psychosis, and other tissue connective diseases with CNS disorder.

Results: Titer of anti-MAP-2 antibody in cerebrospinal fluid was significantly higher in NPSLE patients compared to non NPSLE controls. When the cutoff value was designed as average + 3SD of the controls, the prevalence of anti-MAP-2 antibody in NPSLE patients was 33.3% (8/24), and none of patients with non NPSLE controls (0/18) had an anti-MAP-2 antibody. Furthermore, titer of anti-ribosomal P antibody and IL-6 concentration in cerebrospinal fluid, which are other diagnostic biomarker for NPSLE, were significantly higher in NPSLE patients with anti-MAP-2 antibody compared to NPSLE patients without anti-MAP-2 antibody or non NPSLE controls.

Conclusion: Anti-MAP-2 antibody in cerebrospinal fluid was recognized in 33.3% patients with NPSLE and the appearance was highly specific for NPSLE. We propose that anti-MAP-2 antibody in cerebrospinal fluid is a novel diagnostic biomarker for NPSLE.

MRI in Neuropsychiatric Lupus: Correlations with the 1999 ACR Case Definitions. Minyoung Her1, Dongyook Kim1, Na young Park1, Seong-Kyu Kim2, Lee Sung Won2 and Lee sang Yeo2. 1Inje University, Pusan Paik Hospital, Busan, South Korea, Busan, South Korea, 2Catholic University of Daegu, Daegu, South Korea, Daegu, South Korea, 3Dong-A University, Busan, South Korea, Busan, South Korea.

Background/Purpose: Neurological manifestations in SLE are diverse. Because of its varied manifestations and low prevalence, the ACR has developed nomenclature and case definitions for neuropsychiatric SLE (NP-SLE) to facilitate clinical research. Brain MRI has been used for the evaluation of neurological symptoms. The purpose of this study was to identify characteristic brain MRI findings in NP-SLE and to investigate the association between brain MRI findings and NP-SLE manifestations.

Methods: All brain MRI cases that received the diagnosis of SLE at three tertiary university-based hospitals from August 2002 to August 2013 were screened. 219 brain MRIs with diagnosis of SLE were screened. All clinical manifestations found by brain MRI were retrospectively assessed and were classified as NP-SLE according to the 1999 NPSLE ACR nomenclature and case definitions. In total, 139 brain MRIs in 121 patients with NP-SLE from 2002 to 2013 were retrospectively reviewed. The images were evaluated for the presence of white matter hyperintensity (WMH), gray matter hyperintensity (GMH), parenchymal defects, atrophy, enhancement, and the abnormalities in diffusion-weighted image (DWI). The number, side, and location of WMH, GMH and parenchymal defects were evaluated. The NP-SLE manifestations of each patient were classified according to the 1999 ACR case definitions for NP SLE syndromes. The associations between MRI findings and manifestations of NP-SLE were examined.

Results: In total, 97 MRIs (69.8%) demonstrated abnormalities among the 139 brain MRIs reviewed. There were 164 NP events that encompassed 16 of 19 NP syndromes. The most common NP abnormalities were WMHs. One or more WMHs were found in 78 MRIs (56.1%) among the total 139 MRIs. GMHs were observed in 42 MRIs (32.0%). GMHs tended to involve much larger areas than WMHs. Patients with cerebrovascular disease or seizures were more likely to have GMHs than patients with other NP manifestations. 33 MRIs among 42 GMHs which had GMHs also exhibited WMHs. Parenchymal defects were found in 34 MRIs (24.5%). A trophic was detected in 20 MRIs (14.4%). Brain MRIs were enhanced in 21 of the 122 cases that had undergone enhancement. Patients who had seizures were more likely to demonstrate MRI enhancement than patients with other NP manifestations. DWIs were obtained in 97 MRIs and abnormal DWIs were obtained in 17 MRIs cases. Patients with cerebrovascular disease were more likely to have GMH, parenchymal defects and abnormal DWI than patients with other NP manifestations.

2994

Blood Brain Barrier and Anti-NR2 Antibody in SLE Patients with Cognitive Impairment. Gaurav Gulati1, Philip Iliffand, Vikram Puvenna2, Damir Janigro2 and Michael Luggen3. 1University of Cincinnati College of Medicine, Cincinnati, OH, 2Cleveland Clinic Lerner College of Medicine, Cleveland, OH.

Background/Purpose: Cognitive Impairment (CI) is one of the most common manifestations of neuropsychiatric SLE (NP-SLE) and one of the most devastating. The pathogenesis of CI in SLE is not known, but in animal models, antibody to the NR2 subunit of the N-methyl D-aspartate receptor (NR2) can cause memory impairment. However, this effect can only be demonstrated if the blood brain barrier (BBB) has been disrupted or if the antibody is introduced intracereally. Several studies in SLE patients have failed to find an association of NR2 with CI. None, however, has assessed the integrity of the BBB as a potential pathogenic cofactor. S100B protein is an astrocyte specific protein that has been used as biomarker of BBB disruption in traumatic brain injury and some neurodegenerative disorders. An antibody to this protein may indicate previous exposure to this immunologically privileged protein and might be used as an indicator of preceding BBB disruption. We hypothesized that NR2 antibody is pathogenic in SLE patients only if there evidence of previous or ongoing BBB disruption as indicated by increased levels of S100B or anti-S100B.

Disclosure: M. Her, None; D. Kim, None; N. Y. Park, None; S. K. Kim, None; L. Sung Won, None; L. sang Yeo, None.

2995

Disclosures: None.
Methods: Patients who fulfilled the revised American College of Rheumatology (ACR) criteria for SLE and were stable for at least 4 weeks were recruited from three different settings. Basic demographic, clinical and laboratory data was collected. The Automated Neuropsychological Assessment Metrics (ANAM), a computerized and validated tool, was utilized to measure cognitive function. The Total Troughscore (TTS = number of correct responses/time) was used as the primary outcome measure. CI was defined as a score of less than 1.5 SD below the age, sex, and race matched RA population mean. Patients also had assessment of fatigue, depression, SLE activity and SLE damage using the FACTI fatique score, Becks Depression Inventory (BDI), SLEDAI 2K, and SLICC respectively. Serum was analyzed by established ELISA techniques for anR2 antibody, anti-S100B antibody and intact serum S100B protein.

Results: A total of 57 patients were evaluated. Demographic and clinical data is summarized in Table 1. The age, ethnicity, and family income were significantly different between the two groups (p<0.05). In a multiple regression model using the above independent variables together with simple reaction time and opioid use, no significant effects of aNR2, S100B, or aS100B on decreasing TTS were found. However, aNR2 antibodies significantly decreased TTS at higher, but not lower, levels of S100B (p<0.01, model R² of 0.657, p<0.0001).

Conclusion: Antibody to NR2 may play a role in the pathogenesis of CI in SLE patients, but it does so only if there is disruption of the blood brain barrier as has been previously suggested. Confirmation of these findings and further investigation of the causes of BBB damage in these patients may improve our understanding of this important problem.

ACR Concurrent Abstract Session

Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics III: Updates in Predictors and Outcomes in Systemic Sclerosis

Wednesday, November 19, 2014, 9:00 AM - 10:30 AM

2995

Surrogate Measures of Extent of Intersitial Lung Disease As Measured By Quantitative Radiographic Analysis in Patients with Systemic Sclerosis. Elizabeth Volkman1, Donald Tashkin2, Chi-hong Tseang3, Kim Hyun1, Jonathan Goldin5, Philip J. Clements4, Daniel E. Furst3, Dinesh Kanna, Eric Kleerep1, Michael Roth1 and Robert Elashoff2. 1University of California, Los Angeles, David Geffen School of Medicine, Los Angeles, CA, 2University of California at Los Angeles, Los Angeles, CA, 3University of California, Los Angeles, Department of Medicine, Los Angeles, CA, 4University of California, Los Angeles, Department of Medicine, Los Angeles, CA, 5University of Michigan Health System, Ann Arbor, MI, 6University of California, Los Angeles, Los Angeles, CA.

Background/Purpose: Extent of systemic sclerosis (SSc)-related interstitial lung disease (ILD) predicts disease course, mortality and treatment response. While quantitative analyses of total extent of ILD (QILD) are more sensitive and reproducible than visual assessments of SSc-ILD, these analyses are not widely available. This study evaluates the relationship between disease parameters and QILD scores to identify potential surrogate measures of QILD.

Methods: Using baseline data from the Scleroderma Lung Study I (SLS I) (N=158), multivariate regression analyses were performed using the best subset selection method to identify 1 to 5 variable-models that best predict QILD scores in both whole lung (WL) and the zone of maximal involvement (ZM). These models were subsequently validated using baseline data from SLS II (N=142). SLS I&II did not include patients with clinically significant pulmonary hypertension (PH).

Results: Diffusing capacity for carbon monoxide (DLCO) was the single best predictor of QILD in the WL and ZM in all of the best subset models (Tables 1, 2). Adding other disease parameters to the models did not substantially improve model performance. Forced vital capacity (FVC) did not predict QILD scores in any of the models.

Conclusion: In the absence of PH, DLCO provides the best overall estimate of HRCT-measured QILD in patients from 2 large SSc cohorts. FVC, which is commonly used to monitor disease course in SSc-ILD, may not be the best surrogate measure of extent of QILD.

**Background/Purpose:** Knowledge of mortality risk and predictors is important in systemic sclerosis (SSc) patient care and clinical trial design. There is no validated 5-year mortality model in early diffuse SSc (dcSSc), a high-risk population. The objective of this study was to derive and externally validate a 5-year mortality risk stratification tool in early dcSSc patients.

**Methods:** The derivation cohort was a prospectively enrolled inception cohort of adult early dcSSc patients first seen between 1980 and 2009 and enrolled in a US Scleroderma Center database. Early dcSSc was defined as <2 years from the first SSc symptom and proximal skin thickening. Predefined candidate predictor variables at the first visit (demographic, history, exam, lab values, organ system objective tests) were placed into a stepwise multivariable logistic regression model. Regression diagnostics were performed. Beta-estimates were rounded to the nearest 1, and then summed for a total score, which was then classified into low, moderate, and high risk mortality categories. The external validation cohort was a large UK Scleroderma Center database, with patients meeting identical inclusion criteria and an initial visit between 2000 and 2008. A re-run under the curve (AUC) was calculated to assess discrimination in the derivation and validation cohorts, and stratum-specific chi-square analysis performed.

**Results:** In the US derivation cohort, 760 early dcSSc patients were identified, of whom 388 were Caucasian and had all objective testing required to assess internal organ involvement at the first visit. The mean age was 50.4 ± 13.3 years, 76% female and median disease duration 0.93 years (IQR 0.55–1.33). The mean skin thickness score was 45.4 ± 11.7. After 5 years, 110 of the 388 (28.4%) had died. 144 patients composed the UK validation cohort, with no significant differences in age, gender or skin score from the US cohort. Median disease duration was longer at 1.02 (0.78,1.45) years (p = 0.03). At 5 years 38/144 (26.4%) had died, which was not different (p = 0.65) from the US cohort.

| GI involvement* | 0.93 | 2.42 | 1.39–4.21 | 0.002 | 2 |
| RNA polymerase III antibody | –0.86 | 0.41 | 0.23–0.72 | 0.002 | 2 |
| Anemia (hemoglobin < 12 mg/dL) | 0.62 | 2.17 | 1.25–3.76 | 0.0006 | 2 |

**Total Sum Score**

*defined as any one of: heartburn, pharyngeal pain, abnormal esophagram or manometry, antibiotics for or documented small bowel bacterial overgrowth, small bowel dysmotility by radiographic imaging, pseudo-obstruction, malabsorption or necessity for hyperalimentation. Tnote that RNA polymerase III is protective.

Significant independent predictors of 5-year mortality at first visit were age, gender, tenderness, fibrinogen, GI involvement, RNA polymerase III antibody and anemia (Table 1). The AUC in the US derivation cohort was 0.79 (95% CI 0.74–0.84) for the overall model and 0.74 (0.65–0.82) in the UK cohort. Using the total sum score, risk stratification was defined as low (≤3), moderate (4–7) and high (≥8) risk. The AUC for the 3-level risk stratification in the US derivation cohort was 0.76 (0.72–0.81) compared to 0.68 (0.60–0.76) in the UK validation cohort (p = 0.24). There were no significant differences in mortality rate between each strata of the risk stratification model in the US and UK cohorts.

**Conclusion:** We have developed and externally validated an easy-to-use 3-level risk stratification tool for 5-year mortality in early dcSSc patients. This tool requires only history, exam and bloodwork.

Screening for Interstitial Lung Disease in Systemic Sclerosis: Performance of High-Resolution Computed Tomography with Limited Number of Slices - a Prospective Study. Thomas Frauenfelder, Anna Winkelthner, Thi Dan Linh Nguyen, Rucscandra Dobrota, Stephan Baumberl, Britta Maurer and Oliver Distler.

**Background/Purpose:** Early diagnosis of interstitial lung disease (ILD), currently the main cause of death in systemic sclerosis (SSc), is needed. We performed a prospective validation of a dedicated, 9-slice HRCT protocol with reduced radiation dose for the detection of ILD in patients with SSc.

**Methods:** We analysed 170/205 consecutive patients with SSc. Whole chest HRCT, serving as standard of reference, and the reduced HRCT with 9 slices allocated according to a basal-apical gradient were obtained. ILD presence, extent (>20% vs. <20%), and diagnostic confidence were assessed. The reduced CT was independently analysed by 2 blinded radiologists, who also evaluated image quality. The effective radiation doses and the test performance parameters of the reduced HRCT were calculated.

**Results:** The study cohort included early (n=66), limited cutaneous SSc (n=34) patients, with a median disease duration of 60 months (Q1:Q3 28,120). Standard chest HRCT showed ILD in 77/170 patients. With the reduced HRCT, 68/77 cases with ILD were identified (sensitivity 88.3%, both readers). The accuracy (91.8%-reader1, 94.7%-reader2), diagnostic confidence (98.8%-reader1, 95.3%-reader2) and image quality rates were high (Table 1). Missed cases were exclusively identified (sensitivity 88.3%, both readers). The accuracy (91.8%-reader1, 94.7%-reader2), diagnostic confidence (98.8%-reader1, 95.3%-reader2) and image quality rates were high (Table 1). Missed cases were exclusively identified (sensitivity 88.3%, both readers). The accuracy (91.8%-reader1, 94.7%-reader2), diagnostic confidence (98.8%-reader1, 95.3%-reader2) and image quality rates were high (Table 1).

*ILD was present in 77 patients in standard CT. Correctly estimated extent in reduced CT as compared to standard CT.

**Conclusion:** The above-described reduced chest HRCT protocol reliably detects even mild SSc-ILD in clinical practice, with the advantage of a much lower radiation dose compared to standard whole chest HRCT. This makes it an attractive protocol for periodical screening for ILD in SSc.

Comparison of Systemic Sclerosis Subsets As Predictors of Mortality and Morbidity. Hebah Alhajeri1, Marie Hudson1, Canadian Scleroderma Research Group CSRG1 and Murray Baron2, 1McGill University, Montreal, QC, 2Lady David Institute for Medical Research and Jewish General Hospital, Montreal, QC.

Background/Purpose: Identifying systemic sclerosis (SSc) subsets that predict mortality and morbidity could provide useful prognostic information. We undertook this study to compare the predictive ability of different approaches to subsetting SSc.

Methods: SSc subjects from the Canadian Scleroderma Research Group cohort were studied. Three approaches to subsetting were used: Leroy subsets based on skin involvement (limited (lcSSc) and diffuse cutaneous (dcSSc) subsets), serological subsets (anti-centromere (ACA) and anti-topoisomerase I (ATA) antibody subsets) and unsupervised clustering (but not Leroy classification) predicted mortality, with ACA having better survival than RNAP and ATA 1 having better survival than the 2 other clusters. All three approaches to subsetting predicted FVC < 70% development of ILD: dcSSc was worse than lcSSc, ACA was better than ATA and RNAP, and cluster 1 was better than the other clusters. None of the 3 approaches to subsetting predicted time to PH. Subsetting based on Leroy classification and autoantibodies, but not clusters, predicted time to SF-36 PCS < 40, with ACA worse than ATA.

Conclusion: Different approaches to subsetting provide different prognostic information. Subsetting based on clinical and serological profiles remains a challenge in SSc. In the future, subsetting based on molecular profiles may improve the predictive ability of SSc subsets.

Targeting IL-6 By Both Passive or Active Immunization Strategies Prevents Inflammation-Driven Skin Fibrosis. Jerome Avouac1, Lucille Desalais2, Maxime Frechét1, Mourad Elhai3, Jean François Zagury2 and Yannick Allanore2, 1Paris Descartes University, Rheumatology A Department and INSERM U1016, Cochin Hospital, Paris, France, 2Chaire de Bioinformatique, Laboratoire Génomique, Bioinformatique et Applications, EA 4627, Conservatoire National des Arts et Métiers, Paris, France, 3INSERM U1016, Cochin Institute, Paris, France.

Background/Purpose: Interleukin 6 (IL-6) is a pleiotropic cytokine involved in inflammatory and autoimmune processes. Preliminary data have suggested that IL-6 might contribute to systemic sclerosis (SSc). Our aims are to evaluate the efficacy of both passive and active immunization against IL-6 to reduce skin fibrosis in complementary mouse models of SSc.

Methods: Human serum levels and skin expression of IL-6 were determined by ELISA and immunohistochemistry, respectively. We evaluated the monoclonal IL-6R antibody MR16-1 in the mouse model of bleomycin-induced dermal fibrosis, reflecting early and inflammatory stages of SSc. Six-week-old DBA/2 mice received in parallel subcutaneous injections of bleomycin (0.5 mg/ml) and intraperitoneal (ip.) injection of MR16-1 or control antibody at a dose of 2 mg at day 0 followed by one ip. injection of 1 mg at day 7 and 14. Then, we assessed the merit of MR-16 in the tight skin (Tsk-1) mice, an inflammation-independent mouse model of skin fibrosis. Tsk-1 mice received a first ip. injection of 2 mg of MR16-1 or control antibody at the age of 5 weeks followed by one ip. injection of 1 mg once a week for 5 weeks. Thereafter, because of the drawbacks of anti-cytokine monoclonal antibodies, we developed an innovative strategy using active immunization against a small peptide derived from murine IL-6, which was performed in the mouse model of bleomycin-induced dermal fibrosis. Infiltrating leukocytes, T cells and B cells were quantified, and IL-6 levels were measured in the serum and lesional skin of mice after passive or active immunization.

Results: Serum and skin levels of IL-6 were significantly increased in patients with early SSc. Passive immunization with MR16-1 exerted antifibrotic effects in the mouse model of bleomycin-induced dermal fibrosis; reflecting early and inflammatory stages of SSc. Six-week-old DBA/2 mice received in parallel subcutaneous injections of bleomycin (0.5 mg/ml) and intraperitoneal (ip.) injection of MR16-1 or control antibody at a dose of 2 mg at day 0 followed by one ip. injection of 1 mg at day 7 and 14. Then, we assessed the merit of MR-16 in the tight skin (Tsk-1) mice, an inflammation-independent mouse model of skin fibrosis. Tsk-1 mice received a first ip. injection of 2 mg of MR16-1 or control antibody at the age of 5 weeks followed by one ip. injection of 1 mg once a week for 5 weeks. Thereafter, because of the drawbacks of anti-cytokine monoclonal antibodies, we developed an innovative strategy using active immunization against a small peptide derived from murine IL-6, which was performed in the mouse model of bleomycin-induced dermal fibrosis. Infiltrating leukocytes, T cells and B cells were quantified, and IL-6 levels were measured in the serum and lesional skin of mice after passive or active immunization.

Conclusion: Our results support the relevance of targeting IL-6 in patients with early SSc since IL-6 is overexpressed in early stages of the disease. Targeting IL-6 by both passive or active immunization strategies prevented the development of bleomycin-induced dermal fibrosis in mice. Our results highlight the therapeutic potential of active immunization against IL-6, which is a seductive alternative to passive immunization.

ACR Concurrent Abstract Session

Systemic Sclerosis, Fibrosing Syndromes and Raynaud’s - Pathogenesis, Animal Models and Genes II

Wednesday, November 19, 2014, 9:00 AM – 10:30 AM

S1312
Anti-Fibrotic Effects of a Newly Discovered HGF Receptor Carboxy-Terminal Fragment in Systemic Sclerosis. Yuchiro Shirai1, Ilia Aanelishvili2, Tanjina Akte3, Richard Silver4 and Galina Bogatkevich1. 1Medical University of South Carolina, Charleston, SC, 2Medical University of South Carolina, Charleston, USA, 3Medical University of South Carolina, Charleston, SC.

Background/Purpose: Systemic sclerosis (SSc) is an irreversible fibrotic disorder with interstitial lung disease (ILD) being a major complication and leading cause of mortality. African American SSc patients exhibit higher prevalence of ILD and worse outcomes than those of other races. We previously reported that a cell-protective and antifibrotic factor, hepatocyte growth factor (HGF), is downregulated in bronchoalveolar lavage fluid and plasma from African American SSc-ILD patients compared with white SSc-ILD patients. Here we report a newly identified C-terminal fragment of the HGF receptor, designated as “M10”, as a peptide with robust antifibrotic properties that is lacking in certain African American SSc-ILD patients.

Methods: Lung tissue was collected postmortem from SSc patients with ILD and RNA was extracted from lung fibroblasts. The coding exons of the HGF receptor, MET (mesenchymal-epithelial transition factor), were amplified by PCR, and sequences were analyzed. A denovourises carrying wild type MET gene or the D1398G mutant observed in African American patients were generated. Lung fibroblasts were infected by either type of adenovirus and treated with HGF, transforming growth factor-β (TGF-β), and the M10 peptide. MET phosphorylation, connective tissue growth factor (CTGF), CCN2 and collagen expression was examined by immunoblotting. Potential peptide-protein interactions were modulated in silico.

Results: We have identified the D1398G mutation in a African American SSc-ILD patients whose MET signaling is impaired. When we compared MET phosphorylation following HGF treatment between normal lung fibroblasts expressing wild type or the D1398G MET, we found that the D1398G mutant showed reduced MET phosphorylation. Additionally, normal fibroblasts expressing the D1398G mutant exhibited a diminished reduction in CTGF and collagen expression following HGF treatment compared with wild type. Sequence analysis revealed that the D1398G mutation is located at the terminal amino acid sequence of “DEVD” which is a Caspase-3 cleavage motif, suggesting that the D1398G MET mutant is incapable of generating the terminal 10-amino-acid-fragment of MET, M10. We found that synthetic M10 peptide effectively reduces, in a dose-dependent manner, collagen and CTGF in SSc fibroblasts. Computational molecular modeling based on the peptide-binding sites from protein surfaces predicts that M10 may negatively regulate MET phosphorylation following HGF treatment between normal lung fibroblasts expressing the D1398G mutant and shifted macrophages from M2 phenotype to M1 phenotype. Furthermore, a M10 directly reversed the pro-fibrotic phenotype of normal dermal fibroblasts treated with TGF-β1 and SSc dermal fibroblasts via suppressing the transcription and reducing the mRNA stability of COL1A2 gene, increasing mRNA levels of M MP-1 gene, and decreasing mRNA levels of CTGF gene.

Conclusion: These results suggest that A m10 inhibits the development of experimental dermal fibrosis via reversing the pro-fibrotic phenotype of fibroblasts, dermat microvascular endothelial cells, and immune cells and would be a candidate of new therapeutic drugs against dermal fibrosis of SSc.

Autoantibody-Mediated Raynaud’s Phenomenon: Animal Model and Human Disease. Dana P. Ascherman1, Y unjuan Zang1, Laisel Martinez1, Judith Pignac-Kobinger2, Irene Fernandez2 and Eric L. Greindl2. 1Miami VAMC, Miami, FL, University of Miami, Miami, FL.

Background/ Purpose: Raynaud’s Phenomenon (RP) is frequently seen in autoimmune conditions, but a autoimmune basis for RP has not been established.

Methods: Sera derived from anti-RNP+ individuals were screened for antibodies associated with RP by immunoprecipitation, western blot, and ELISA. Autoantigens targets were then identified by mass spectrometry. Biological effects of antigen-specific monoclonal antibodies as well as human and murine antisera were assessed in in vitro and in vivo models of experimental dermal fibrosis via reversing the pro-fibrotic phenotype of fibroblasts, dermal microvascular endothelial cells, and immune cells and would be a candidate of new therapeutic drugs against dermal fibrosis of SSc.

Conclusion: A m10 inhibits the development of experimental dermal fibrosis via reversing the pro-fibrotic phenotype of fibroblasts, dermat microvascular endothelial cells, and immune cells and would be a candidate of new therapeutic drugs against dermal fibrosis of SSc.

Am80 Ameliorates Bleomycin-Induced Dermal Fibrosis By Suppressing the Pro-Fibrotic Phenotype of Fibroblasts, Endothelial Cells, and Immune Cells. Tetsuo Toyama1, Y oshhide Asano2, Takuro Takahashi3, RyosukeSaigusa3, Y oheichimura4, Takashi Taniguchi5, Shinji Noda5, Kaname Akama3, Shinichi Sato3, Takaumi Kadono6 and Koichi Shudo7. 1University of Tokyo Graduate School of Medicine, Tokyo, Japan, 2Research Foundation ITSUU Laboratory, Tokyo, Japan.

Background/Purpose: A m80 is a synthetic retinoid serving as an agonist for retinoic acid receptor α/β with chemical and pharmacological advantages over all-trans retinoic acid, such as higher chemical stability, a lower affinity for cellular retinoic acid-binding protein, and a lack of affinity for retinoid acid receptor-γ. A m80 has been shown to modulate the pathological processes of various autoimmune and inflammatory diseases and their animal models. The primary objective of the study was to investigate the effect of A m80 on dermal fibrosis of a bleomycin (BLM)-induced murine model of systemic autoimmune disease (SSc), normal dermal fibroblasts treated with TGF-β1 and SSc dermal fibroblasts.

Methods: A BLM-induced murine model of SSc was generated with wild type C57BL/6 mice in the presence or absence of oral administration of A m80. The mRNA and protein levels of target molecules were determined by quantitative reverse transcription-PCR, immunostaining, and immunoblotting in the skin and cultured cells. Th1/Th2/Th17 polarization of immune response and macrophages polarization were evaluated by flow cytometry.

Results: A m80 significantly decreased tissue fibrosis and mRNA levels of the Tgfb and Cgfl genes in the lesional skin of BLM-treated mice. In response to A m80, the expression levels of cytokines and chemokines, including IL-4, IL-10, IL-13, IL-17A, TNF-α, IFN-γ, and MCP-1, in the lesional skin were decreased and the differentiation of naïve T cells into cytokine producing effector T cells, such as Th1/Th2/Th17 cells, and regulatory T cells were suppressed in BLM-treated mice. In addition, the infiltration of macrophages, mast cells, and T cells was attenuated by A m80 in BLM-treated mice. A m80 also exerted on dermal microvascular endothelial cells through attenuating the induction of endothelial-to-mesenchymal transition and the expression of intercellular adhesion molecule-1, and shifted macrophages from M2 phenotype to M1 phenotype. Furthermore, A m80 directly reversed the pro-fibrotic phenotype of normal dermal fibroblasts treated with TGF-β1 and SSc dermal fibroblasts via suppressing the transcription and reducing the mRNA stability of COL1A2 gene, increasing mRNA levels of M MP-1 gene, and decreasing mRNA levels of CTGF gene.

Conclusion: These results suggest that A m80 inhibits the development of experimental dermal fibrosis via reversing the pro-fibrotic phenotype of fibroblasts, dermal microvascular endothelial cells, and immune cells and would be a candidate of new therapeutic drugs against dermal fibrosis of SSc.

**Essential Role for Alternately Spliced Tenasin C and TL R4 Signaling in Persistent Organ Fibrosis.** Swati Bhattacharyya1, Wenxia Wang1, Luisa Morales-Nebreda1, Kajita Lakota2, Robert Lafayitis3, Monica E. Hinchcliff3,4, Scott Budinger3,4, Zenshiro Tanaki5 and John Varga1.

**Background/Purpose:** Transforming growth factor-beta stimulates collagen synthesis and myofibroblast differentiation, and is implicated as a key initiating factor in pathological tissue remodeling in scleroderma. However, the mechanistic role for the persistence fibrotic response associated with scleroderma is not well understood. Recent studies provide evidence for activated innate immunity in patients with scleroderma. Many alternately spliced factors that govern normal embryonic and fetal development are currently recognized as being central to postnatal repair and injury responses. We hypothesized that tissue injury in scleroderma leads to generation and accumulation of alternately spliced extracellular matrix molecules such as tenasin C that are recognized by, and serve as endogenous ligands for TLR4 to drive persistent fibrosis.

**Methods:** Tissue expression of tenasin C was investigated in scleroderma skin biopsies by microarray, immunofluorescence and real-time qPCR. Tenasin C was assayed in 3-D human skin equivalents reconstituted with scleroderma fibroblasts and in scleroderma serum. Cellular responses elicited by tenasin C in human and mouse skin fibroblasts and in 3-D organotypic human skin equivalents were examined. The role of tenasin C in scleroderma skin and lung fibrosis was investigated using tenasin C-null mouse.

**Results:** Levels of an alternately spliced full-length tenasin C isoform (TN-FL) were markedly elevated in scleroderma serum and skin biopsies, as well as in fibroblastic and lung tissues from mice. TN-FL mRNA levels correlated with the skin score. The splicing factor serine/arginine-rich (SR)-rich splicing factor SRSF6, implicated in alternate splicing of tenasin C, was elevated in scleroderma fibroblasts as well as in scleroderma fibroblasts populating skin equivalents. Treatment with TGF-β stimulated the expression of both SRSF6 and TN-FL. In vitro, TN-FL stimulated collagen synthesis and myofibroblasts differentiation, and induced dermal sclerosis in skin equivalents. All of these profibrotic responses were abolished by genetic or pharmacological disruption of TLR4 signaling. Importantly, tenasin C-null mice treated with bleomycin were protected from development of skin and lung fibrosis and loss of lung compliance.

**Conclusion:** Increased SRSF6-driven alternate splicing of tenasin C leads to aberrant TN-FL accumulation in scleroderma. TN-FL triggers TLR4-dependent fibroblast activation, contributing to intracatable skin and lung fibrogenesis. Disrupting the tenasin C-TLR4 signaling axis by preventing tenasin C accumulation through SRSF6 blockade, or by blocking TLR4 signaling using selective small molecule inhibitors, represents appealing novel strategies for attenuating progressive fibrosis as treatment for scleroderma.

**Activation of the Thromboxane A2 Receptor By 8-isoprostane Inhibits the Pro-Angiogenic Effect of Vascular Endothelial Growth Factor in Scleroderma.** Pei-Suen Tsou1, George Zakhem2, Beatrix Balogh2, M. Asif Amin3, Phillip Campbell3, Gautam Edhayan4, Ray A. Qhara5, Elena Schiopu5, Dinesh Khanna3,6, Alisa E. Koch7 and David A. Fox3,4.

**Background/Purpose:** Scleroderma (SSc) is a complex disease characterized by inflammation, vasculopathy, and excessive deposition of extracellular matrix. Various studies have demonstrated a paradoxical increase in angiogenic factors and a decrease in the vascular endothelial growth factor (VEGF), in both the skin and serum of patients with SSc. Despite this, angiogenesis does not occur normally. 8-isoprostane is an oxidized lipid created by excessive oxidative stress, and has been shown to be elevated in SSc. The thromboxane A2 receptor (TXAR) and ROCK pathway, which can be activated by 8-isoprostane (8-IP), inhibits VEGF-induced endothelial cell (EC) differentiation and migration. However, its role in SSc has not been examined. In this study we determined whether the TXAR pathway was activated by 8-IP in SSc ECs. Its effect on VEGF-induced angiogenesis was also determined.

**Methods:** Dermal ECs were isolated from punch biopsies from healthy subjects or patients with diffuse cutaneous SSc. Angiogenesis was assessed by chemotaxis and in vitro microtube formation assays. TXAR expression was determined by qPCR and Western blotting. Knockdown studies were performed using TXAR siRNAs.

**Results:** SSc patient had significantly higher 8-IP plasma levels (60.9-8.4 pg/ml) compared to healthy subjects (24.9-5.0 pg/ml, p<0.05). Increased oxidative stress was detected in SSc ECs as increased 8-IP in SSc EC conditioned media and excessive superoxide in SSc ECs were observed. In healthy ECs, 8-IP inhibited VEGF-induced EC migration, and the inactivation of TXAR or ROCK pathways restored VEGF-induced angiogenesis inhibited by 8-IP. In SSc ECs, VEGF did not induce EC migration, however, addition of the TXAR or ROCK inhibitors restored the pro-angiogenic effect of VEGF. This was further confirmed by TXAR siRNA experiments which showed TXAR knockdown led to inhibition of VEGF-induced migration towards VEGF while the SHAM-transfected ECs did not. We then measured ROCK activity in healthy and SSc ECs before and after VEGF or 8-IP stimulation. Basal ROCK activity was significantly higher in SSc ECs compared to healthy ECs. Moreover, 8-IP-induced ROCK activation was significantly higher in SSc ECs while VEGF induced significantly higher ROCK activation in healthy ECs. The expression of key players in this pathway was also examined. The protein expression of TXAR, RhoA, ROCK1/2 were all elevated in SSc ECs compared to healthy ECs.

**Conclusion:** We show that 8-IP inhibits VEGF-induced migration in healthy ECs through the TXAR/ROCK pathway. ECs not only produce high levels of 8-IP, but also show elevated expression of TXAR and RhoA/ROCK levels. This could explain the increased activation of the TXAR pathway in terms of ROCK activity in SSc ECs compared to healthy ECs. This hyper-activation leads to inhibition of VEGF-induced EC migration, as using the TXAR or ROCK inhibitor, as well as specific knockdown of TXAR, results in restoration of VEGF activity. These results suggest that the TXAR pathway plays a crucial role in angiogenesis and that 8-IP is not just a by-product as a result of oxidative stress, but instead plays a significant role in impaired angiogenesis that characterizes SSc.

**Can Knee Pain Be Prevented through Diet and Exercise Among Those at High Risk? the Look Ahead Study.** Daniel White1, Tuhiha Negi2, W. Jack, Rejeski3, Michael Wilkup3, Cora E. Lewis4, Michael Nevitt5, Capri experiment6 and David T. Felson7.

**Background/Purpose:** There is accumulating evidence that a low-carbohydrate, higher-protein diet rich in vegetables and fruits is associated with a lower risk of developing knee osteoarthritis (OA). We examined whether changes in diet and physical activity (PA) predicted changes in knee pain in the Look AHEAD study, a multi-center randomized intervention trial of an intensive lifestyle intervention (ILI) vs. diabetes support and education (DSE) comparison group in adults with a BMI >25 kg/m2 and type II diabetes. Participants in the ILI had goals of reducing weight by 7% and participating in >175 minutes/week of physical activity by one year. We included subjects with knee pain at baseline and examined to what extent the ILI reduced weight and increased PA may have prevented the development of knee pain among those at high risk. We examined whether an intensive weight loss and exercise intervention prevented the development of knee pain among obese adults with type II diabetes, a group at risk for knee pain due to excess weight.

**Methods:** We carried out a secondary analysis of the Look AHEAD study, a multi-center randomized intervention trial of an intensive lifestyle intervention (ILI) vs. diabetes support and education (DSE) comparison group in adults with a BMI >25 kg/m2 and type II diabetes. Participants in the ILI had goals of reducing weight by 7% and participating in >175 minutes/week of physical activity by one year. We included subjects with knee pain at baseline and examined to what extent the ILI...
group protected against developing knee pain at year 1 and 4. Knee pain was assessed by asking “Have you had any pain or discomfort in your knees in the past month?” In a second separate analysis, we examined whether meeting treatment goals, i.e., weight loss only, physical activity only, or both weight loss and physical activity, reduced the risk of developing knee pain compared with those not meeting any goal at year 1 and 4. This second analysis was performed in a subset of 989 participants whose clinic sites provided an accelerometer.

**Results:** Of the 2998 participants with no knee pain at baseline (age 58.5 ± 6.7, men 44.9%, BMI 35.1 ± 5.6) 50.1% were assigned to the ILI group and the remainder to the DSE. Subject characteristics were similar between groups at baseline. At year 1, ILI participants were 15% less likely to develop knee pain compared with. At year 4, this decreased to 5% and was not statistically significant. In the second analysis, participants meeting both weight loss and physical activity goals had 47% less risk of developing knee pain at year 1. Only those meeting the weight loss goal at year 1 had less risk that met statistical significance of developing knee pain at year 4.

**Conclusion:** An intensive lifestyle intervention of diet and exercise prevented the development of knee pain among those at high risk in the short-term. Weight loss appears to have the most important preventing for the development of knee pain over four years.

**Table:** (A) Association of an Intensive Lifestyle Intervention vs. Diabetes Support and Education control with developing knee pain (n = 2998). (B) Association of meeting treatment goals at one year with the development of knee pain at one and four years among all participants who were an accelerometer (n = 989).

**Stem Cell Augmentation for Cardiovascular Risk in Rheumatoid Arthritis.** Nidhi Garg1, Ashit Synge2 and Pawan Krishan1. 1Punjab University Patala, India, Patala, India, 2Healing Touch City Clinic, Fortis Multispecialty Hospital, Chandigarh, India.

**Background/Purpose:** Bone marrow derived stem cells, endothelial progenitor cells (EPCs), protect against atherosclerotic vascular damage by overcoming endothelial damage. However, EPCs are depleted in RA and contribute to the enhanced cardiovascular (CV) risk. Therapeutic potential of augmenting EPCs to treat the heightened CV risk of RA has not yet been exploited. We aimed to investigate the effect of rosuvastatin on EPCs population, endothelial dysfunction, nitrite, adhesion molecules and on markers of inflammation in RA.

**Methods:** 50 RA patients were randomized to receive 24 weeks of treatment with rosuvastatin (10mg/day, n = 25) or placebo (n = 25) as an adjunct to existing stable antirheumatic drugs. EPCs (CD34+/CD133+) were quantified by Flow Cytometry. Flow mediated dilatation (FMD) was assessed by AngioDefenderTM (Everest Genomic Ann Arbor, United States). Inflammatory measures included DAS28, CRP, ESR and Pro-inflammatory cytokines (TNF-α, IL-6 and IL-1) were measured at baseline and at 12 weeks. Estimation of serum nitrite, Lipids, and adhesion molecules (ICAM-1 and VCAM-1) was done at baseline and after treatment.

**Results:** At baseline, inflammatory measures, pro-inflammatory cytokines, adhesion molecules and nitrite levels were elevated and EPCs and endothelial function were impaired among both groups. At 24 wks: DAS28, ESR, CRP, TNF-α and IL-6 improved significantly (p < 0.05) in the rosuvastatin group. Concentration of serum nitrite (p = 0.02) and ICAM-1 (p = 0.01) was significantly lower in the rosuvastatin group compared with placebo. EPCs increased significantly from (CD34+/CD133+) 0.01 to 0.03 (p = 0.01). ICAM-1 (r = 0.47, p = 0.01) after treatment with rosuvastatin as compared with placebo and after 24 wks percentage change in EPCs was 71.4% and 22.2% in the rosuvastatin and placebo groups respectively (Fig.1). After treatment with rosuvastatin there was significant improvement in FMD (p < 0.01) as compared to placebo. Rosuvastatin exerted positive effect on lipid spectrum by significantly increasing HDL cholesterol levels (p = 0.01) and decreasing LDL cholesterol (p = 0.02). Significant inverse correlation was observed between EPCs and CRP (r = -0.44, p = 0.02) and TNF-α (r = -0.42, p = 0.03). ICAM-1 (r = -0.45, p = 0.03) and FMD (r = 0.47, p = 0.01) after treatment with rosuvastatin.

**Conclusion:** First study to show that rosuvastatin augments EPCs population in RA mediated by lowering of the levels of cytokines, especially IL-6 and TNF-α, which downregulates adhesion molecule, CRP and nitric oxide production. This defines a novel mechanism of rosuvastatin treatment.
in patients with RA: the augmentation of EPCs with improvement in inflammatory disease activity and endothelial dysfunction. The augmentation of EPCs by rosuvastatin represents a fascinating new approach for the management of RA.

3010

Background/Purpose: Patient-initiated services in rheumatology have been found to be cost-saving without compromising the clinical or psychosocial well-being of patients with rheumatoid arthritis. Self-monitoring is a technique used in many other long-term conditions and is associated with reductions in healthcare utilisation and mortality and has been found to be satisfactory from the patient's perspective. The aim of this study was to evaluate the efficacy of a service which integrates self-monitoring into patient-initiated follow-ups for patients with RA or PsA on methotrexate; in terms of healthcare utilisation and clinical outcomes, using a mixed methods approach including a randomised controlled trial (RCT) and qualitative semi-structured interviews.

Methods: One hundred patients with RA or PsA (according to ACR/EULAR/ESPOAR criteria) on methotrexate were randomised to either an intervention group or usual care. All participants were assessed over 6 blood tests. Those in the intervention group attended one training session where they were taught how to monitor their blood test results and which symptoms and side effects they should report. These participants had no scheduled appointments with their rheumatology nurse during the trial period, but continued with their consultant appointments as usual. Blood test results were sent to intervention participants and along with their assessment of symptoms and side effects; patients initiated a review with their nurse, when necessary. If these reviews were required an immediate outpatient appointment was made. Healthcare utilisation was monitored throughout the trial period. Poisson regressions and multi-level modelling were used to explore the impact of the intervention on healthcare usage and clinical outcomes.

Results: There were no significant differences in clinical or demographic variables between the two groups at baseline. A cross the trial period 77% of decisions made by intervention participants were considered to be safe. At the end of the trial period participants in the intervention group had 54.55% fewer hospital appointments with their nurse specialist (p < 0.0001). There were no significant differences in the number of appointments with the rheumatologist or GP. Levels of pain, fatigue, ESR, CRP and disease activity did not differ between groups (p > 0.05). Intervention participants were positive about the new model of care, valuing its efficiency and tailored approach. The service allowed patients to gain new knowledge and use this information along with the skills they obtained to take control of their health and arthritis.

Conclusion: After brief training patients with RA and PsA can successfully understand and interpret their blood test results and use this information along with reports of their symptoms and side effects to initiate appropriate reviews with their rheumatology nurse. Participants in the intervention group had fewer hospital appointments with their nurse specialist with no detrimental effects to their clinical status and with no increase in visits to the rheumatologist or GP. This model of care offers a viable alternative for reducing in healthcare utilisation and mortality and has been found to be cost-saving without compromising the clinical or psychosocial status with patients (52 matched pairs of female patients and controls, age: 44 ± 7 yrs, BMI: 24 ± 4 kg/m²).

DT gait analysis was performed in 80 elderly patients (age 68 ± 14 yrs, BMI 25 ± 5 kg/m²), suffering from gait instability, memory impairment, recurrent falls.

Results: Study 1: In knee osteoarthritis two gait variables are highly significant and relevant: area under the ROC curve (SR: 0.79 ± 0.05, SW: 0.78 ± 0.06).

Study 2: In Parkinson’s disease two gait variables are highly significant and correlated to motor score: SR (r = 0.59, p < 0.01); CCR (p = 0.65, p < 0.003).

Study 3: Fibromyalgia patients ROC curves confirm the utility of SF (0.74 ± 0.04); SR (0.68 ± 0.05) and CCR (0.69 ± 0.05) in the identification of fibromyalgia patients.

SR is correlated to the Fibromyalgia Impact Questionnaire (r = 0.33, p < 0.01).

SR is correlated to cognitive dysfunction measured by the Copping Strategy Questionnaire (r = 0.31, p < 0.003).

CCR is correlated to pain (weekly VAS: r = -0.33, p < 0.01).

Study 4: Gait exhibited no abnormality under ST in 13 patients. Gait abnormalities occurred under DT in each patient, moreover the decrease of one or more of the following gait variables (WS, SR, SF) alerted the clinician to an underlying neurological pathology.

Conclusion: The Single Task Gait Analysis condition is well adapted to knee osteoarthritis (SR and SW: a measurement of shock wave), to Parkinson’s disease (SR, CCR: a measurement of kinesia); to fibromyalgia patients (SR, SF, CCR: a method for the identification of homogenous subgroups). Gait Analysis Test under Dual Task conditions is of major interest in exploring the cognitive reserve and explaining gait instability in the elderly.

Ambulatory Gait Analysis in Clinical Practice: Single or Dual Task Conditions? Bernard Auvinet, Claude Touzard and Vincent Goeb. 1Polyclinic, LAVAL, France; 2Hospital of LAVAL, LAVAL, France; 3Amiens University Hospital, Amiens, France.

Background/Purpose: Interest in ambulatory gait analysis is increasing thanks to validated gait analysis apparatus dedicated to clinical practice. Such methodology has to be reproducible, sensitive, specific and pertinent. Traditionally gait analysis was carried out during a walking test with no additional tasks (called single task [ST]). Recently due to the fact that gait control involves the cognitive domain, gait analysis has additionally been carried out using the dual task paradigm, when a task demanding attention is performed during walking - this type of gait analysis is known as Dual Task (DT). We hypothesise that gait analysis under ST or DT conditions has to be chosen according to the objectives of the clinician, as well as that of the choice of gait variables.

Methods: Locometrix is a validated accelerometric device which allows the measurement of the following gait variables: walking speed (WS, m/s), stride frequency (SF, Hz), stride length (SL, m), step symmetry (SS, dimensionless), stride regularity, an index of similarity of successive strides (SR, dimensionless), crano-caudal power (CCP, W/kg), high frequency energy modulus at heel contact (HFEM, %): a measurement of shock wave (SW).

ST gait analysis was performed in three pathological conditions: 1- knee osteoarthritis compared to a control group (41 patients, age: 65 ± 10 yrs, BMI: 28.4 ± 4 kg/m², mean Lequesne index: 9 ± 4.24); 2- newly diagnosed Parkinson patients with no treatment, compared to a control group (22 patients, age: 69.9 ± 9 yrs, BMI: 26.3 ± 3 kg/m², mean motor score: 23.5 ± 3.0); 3- Fibromyalgia patients (52 matched pairs of female patients and controls, age: 44 ± 7 yrs, BMI: 24 ± 4 kg/m²).

DT gait analysis was performed in 80 elderly patients (age 68 ± 14 yrs, BMI 25 ± 5 kg/m²), suffering from gait instability, memory impairment, recurrent falls.

Results: Study 1: In knee osteoarthritis two gait variables are highly significant and relevant: area under the ROC curve (SR: 0.79 ± 0.05, SW: 0.78 ± 0.06).

Study 2: In Parkinson’s disease two gait variables are highly significant and correlated to motor score: SR (r = 0.59, p < 0.01); CCR (p = 0.65, p < 0.003).

Study 3: Fibromyalgia patients ROC curves confirm the utility of SF (0.74 ± 0.04); SR (0.68 ± 0.05) and CCR (0.69 ± 0.05) in the identification of fibromyalgia patients.

SR is correlated to the Fibromyalgia Impact Questionnaire (r = 0.33, p < 0.01).

SR is correlated to cognitive dysfunction measured by the Copping Strategy Questionnaire (r = 0.31, p < 0.003).

CCR is correlated to pain (weekly VAS: r = -0.33, p < 0.01).

Study 4: Gait exhibited no abnormality under ST in 13 patients. Gait abnormalities occurred under DT in each patient, moreover the decrease of one or more of the following gait variables (WS, SR, SF) alerted the clinician to an underlying neurological pathology.

Conclusion: The Single Task Gait Analysis condition is well adapted to knee osteoarthritis (SR and SW: a measurement of shock wave), to Parkinson’s disease (SR, CCR: a measurement of kinesia); to fibromyalgia patients (SR, SF, CCP: a method for the identification of homogenous subgroups). Gait Analysis Test under Dual Task conditions is of major interest in exploring the cognitive reserve and explaining gait instability in the elderly.

Needs Assessment Survey - Evaluation of Sexual Dysfunction Among Patients at a Tertiary Rheumatology Clinic. Sharon Wesner Peleg, Ori Patay, Buria Ya'ini and Jacob N. Abin. 1Tel Aviv Sourasky Medical Center, Tel Aviv, Israel; 2Tel-Aviv Medical Center, Sackler Faculty of Medicine, Tel-Aviv University, Tel-Aviv, Israel.

Background/Purpose: Sexual function is a major component of well-being and is adversely affected by many disease states. Previous studies have demonstrated various aspects of sexual dysfunction among rheumatological patients. These may include reduced libido, pain upon intercourse (dysparunia) and erectile dysfunction; tenderness, limitations of range of motion and depression may have a compounding negative effect. In a previous study we have demonstrated aspects of sexual dysfunction found among fibromyalgia patients. The aim of the current preliminary study was to evaluate aspects of sexual dysfunction among rheumatological patients. We also wished to evaluate the needs of rheumatological patients in sexological counseling, in order to assess the need for establishing a reproductive health clinic at our rheumatology center and design future interventions in this field. A similar approach has been previously used for evaluation the needs of cancer patients.
Methods: Patients: patients were recruited among those attending the rheumatology clinic at the Tel Aviv Sourasky Medical Center from a broad range of rheumatological diagnoses. Participants filled out the following questionnaires:

1. A demographic questionnaire
2. Self-report Sexual questionnaire which was translated into Hebrew and adapted for the needs of the patients at the rheumatology institute. This questionnaire included questions regarding common domains of sexual dysfunction, including decreased libido, difficulty achieving arousal, difficulty in achieving an erection (males) or vaginal dryness (females) pain during intercourse, difficulty in achieving an orgasm, and feeling unattractiveness sexually.

Results: Forty three patients were recruited, (8 males and 35 females). The most frequent age group of the patients was 41-50.

Diagnoses included Rheumatoid arthritis (50%), Osteoarthritis (32%), Fibromyalgia (13%), Systemic Lupus Erythematosus (3.2%) Psoriatic arthritis (13%). Other: 31% reported being currently active sexually.
41% expressed interest in receiving attention for their sexual issues by the attending rheumatologist and 19% would be interested in receiving specialized sexual consultation with their partner, in the context of the rheumatology follow up.

A mong female patients, 25.7% reported a decrease in libido. 17.1% reported pain during sexual intercourse and 17.1% reported difficulty achieving sexual arousal. 14.3% reported vaginal dryness and a decrease sense of attractiveness respectively. 11.4% reported difficulty in achieving an orgasm.

Conclusion: Sexual dysfunction is highly prevalent among rheumatology patients. While not routinely evaluated in clinical practice, this issue appears to be pertinent for many patients who also express interest in receiving specific advice and treatment, as part of their rheumatological follow up. Rheumatological health care providers should be aware of this important aspect of the quality of life of their patients and should feel comfortable about raising the topic during the course of follow up. Further research is warranted into the specific causes of sexual dysfunction in various rheumatological populations and regarding the optimal treatment of these problems.

The Reserve Capacity Model in Patients with Rheumatoid Arthritis: Understanding the Relationship of Socioeconomic Status, Psychosocial Resources, Mood, and Pain.

Desiree Azizoddin1, Taylor Draper1, Sarah Ormseth1, Perry M. Nicassio2, Michael R. Irwin1, Michael Weisman2 and Hilary Wilson1.

2Cedars-Sinai Medical Center, Los Angeles, CA.

The Reserve Capacity Model in Patients with Rheumatoid Arthritis: Understanding the Relationship of Socioeconomic Status, Psychosocial Resources, Mood, and Pain.

Background/Purpose: The reserve capacity model is a framework for understanding how low SES may affect health outcomes through both positive and negative emotions separately and the depletion of psychosocial resources. The purpose of this study was to explore the reserve capacity model in persons with rheumatoid arthritis, using structural equation modeling (SEM; see Figure 1). It was hypothesized that SES would be negatively related to self-reported pain directly and/or indirectly through the potential mediators of positively related psychosocial resources (reserve capacity) and negatively related negative mood.

Methods: Data of 106 participants were drawn from a randomized comparative efficacy trial of psychosocial interventions for RA. In the hypothesized model, SES (years of education and annual income) predicted pain (VAS and Rapid Assessment of Disease Activity in Rheumatology total joint score) through reserve capacity (Personal Mastery Scale, A rthritis Helplessness Index, and Social Provisions Scale), and negative mood (Hamil ton Depression Rating Scale, Perceived Stress Scale and the Positive and Negative Affect Schedule), using EQS 6.1 to evaluate the structural model.

Results: SEM revealed a confirmed the hypothesized relations among model constructs (see Figure 1). Higher SES was positively associated with reserve capacity, which predicted lower levels of negative mood and related directly and positively to pain severity. The indirect effect of SES on pain via reserve capacity and negative mood was significant (β indirect = –.10, p = .027). Evidence supported a partial mediation of reserve capacity and negative mood between SES and pain, as the direct effect of SES on pain remained significant after controlling for the attenuating mediators of reserve capacity and negative mood.

Conclusion: These findings underscore the importance of a multi-dimensional framework in evaluating pain in RA using a structural-equation approach. The mediating variables of reserve capacity and negative mood may play major roles in explaining pain in RA, and represent modifiable factors for targeted interventions.

Does the Order or Amount of Risk-Benefit Information Presented Influence Patients' Perceived Value of a Proposed New Medication? Liana Fraenkel1, Richard Street2, Harjinder Chowdary3, Sarah Swift4 and Ellen Peters5.
1Yale University School of Medicine, Veterans Affairs Connecticut Healthcare Systems, New Haven, CT, 2Texas A & M University, College Station, TX, 3Yale University, New Haven, CT, 4Ohio State University, Columbus, OH.

Background/Purpose: The order and amount of information has been shown to influence risk perceptions related to hazards. In this study we sought to examine whether order and amount of risk and benefit information influences patients' perceived value of a proposed new medication.

Methods: We created 5 videos of a physician describing a new medication. The videos were identical except for the order and number of side effects (SEs) and benefits presented (see Table). Subjects with a systemic inflammatory rheumatic disease were randomly assigned to view one of the videos. Perceived medication value (PMV) was assessed by having subjects choose: the risks outweigh the benefits, the risks and benefits are equally balanced or the benefits outweigh the risks. We subsequently examined whether differences in the order and amount of information was associated with subjects' PMV. This outcome was chosen because one's overall impression more strongly predicts behavior than recall of verbatim information. We also examined the association of demographic characteristics (age, minority status, and difficulty paying for medications), attitudes towards illness and treatment (factor analysis of illness perceptions, patient activation and trust resulting in 4 factors: worry about illness, perceived treatment efficacy, impact of illness, patient activation), and current medications on PMV using bivariate analyses.

Results: Of the 242 patients recruited, 40% minority (African American and/or Hispanic). In bivariate analyses, the order and number of SEs and benefits, current use of prednisone, and minority status and difficulty paying for medications were all significantly associated with PMV. This outcome was chosen because one's overall impression more strongly predicts behavior than recall of verbatim information. We also examined the association of demographic characteristics (age, minority status, and difficulty paying for medications), attitudes towards illness and treatment (factor analysis of illness perceptions, patient activation and trust resulting in 4 factors: worry about illness, perceived treatment efficacy, impact of illness, patient activation), and current medications on PMV using bivariate analyses.

Variables found to be significant (p < .05) were included in a multinomial logistic regression model. Because of the known influence of numeracy on risk perception, all analyses were stratified by high versus low subjective numeracy (dichotomized at the median).

Results: 389 subjects participated; mean (SD) age = 55 (14), 75% female, 40% minority (African American and/or Hispanic). In bivariate analyses, the order and number of SEs and benefits, current use of prednisone, and minority status were associated with PM V in subjects with high numeracy (n = 242). Presenting SEs first or between benefits were both associated with more negative PMV compared to the reference video (3 benefits followed by 6 SEs) (See Table). Among subjects with low numeracy (n = 142), the order and...
number of risk and benefits presented were not associated with PMV. In bivariate analyses, use of a biologic, difficulty paying for medications, perceived treatment efficacy, patient activation, and minority status, were associated with PMV in subjects with low numeracy. Except for current use of a biologic, all remained significant in the multivariate model (see Table).

Conclusion: Order and amount of information matter, but only in patients with high subjective numeracy. Minority patients have a much more negative PMV compared to Caucasian, non-Hispanic patients, regardless of their level of numeracy.

### Table: Multinomial logistic regression model examining association of risk/benefit presentation and patients characteristics on perceived medication value.

### 3015 Evaluation of the effic Educational Needs Assessment Tool (ENAT) Focused Patient Education on Health Outcomes in Patients with Rheumatoid Arthritis - a Randomised Controlled Trial.

Adeyale O. Adebayo1, Dawn Johnson1, Hardware Bernardette2, Claire Hale2, and Mwidi Ndosi2.

1. University of Sheffield, Sheffield, United Kingdom
2. Barnsley Hospital NHS Foundation Trust, Barnsley, United Kingdom
3. Barnsley Hospital NHS Foundation Trust, Barnsley, United Kingdom
4. University of Leeds, Leeds, United Kingdom

Background/Purpose: The Educational Needs Assessment Tool (ENAT) is a quick and simple, self-completed questionnaire that ensures that patient education is relevant, appropriate and timely for people with Rheumatoid Arthritis (RA). It has been validated for use in RA and six other rheumatic diseases and has been cross-culturally adapted into nine European languages. Our aims were (i) to evaluate the effectiveness of ENAT focused patient education on self-efficacy, patient knowledge and health outcomes (physical function, symptoms, role/work, social interaction and psychological status/affect) (ii) to evaluate the usability of the ENAT in clinical practice, from both a practitioner and patient perspective.

Methods: This was a mixed methods (quantitative and qualitative) study conducted in seven rheumatology centres across the United Kingdom. Patients were randomised to either the ENAT group (EG) where patients completed the ENAT which was then used as a template by the Nurse Practitioner (NP) to meet their educational needs; or usual care (UC) by NP without the ENAT. Patients were seen at baseline then at weeks 16 and 32. The outcomes were self-efficacy (ASES), health status (AIM2-SF) and patient knowledge (PKQ). The primary outcome was self-efficacy (ASES) at week 32.

Results: A total of 132 patients were entered into the study of which 70 received ENAT (53%) and 62 usual care (47%). At week 16, there were no significant between-group differences. By week 32, the ASES mean scores, were higher for the ENAT group than the usual care group; ASES-Pain, MD = 4.36 (95%CI: 1.17, 7.55), t = 2.72, p = 0.008; ASES-Other symptoms, MD = 5.84 (95%CI: 2.07, 9.62), t = 3.07, p = 0.003. (Bonferroni-adjusted P-value = 0.025 for significance at the alpha level). Trends over time revealed significant decrease in the overall ENAT score for all domains (managing pain, movement, arthritis process, self-help measures and support) except the feelings domain. The decrease in the total ENAT score by the end of the study, indicates that patients' educational needs were being met effectively.

Conclusion: This is the first study to report the effects of ENAT-focused education in people with RA. The results of the primary outcome (ASES-Pain and ASES-Other symptoms) suggest that the ENAT could be a useful addition to usual care.

### 3016 Measuring the Impact of an Early RA Support and Education Program Using a Program Evaluation with Patient Identified Outcomes.

1. Hospital for Special Surgery, New York, NY.
2. Hospital for Special Surgery Weill Cornell Medical College, New York, NY.

Background/Purpose: The Early RA Support and Education Program addresses the unique psycho-educational needs of people recently diagnosed (<2yr) with RA. This free monthly program is co-facilitated by an MSW and RN and was developed based on a needs assessment with patient input; it features an RA- focused lecture followed by a support group, aimed at enhancing emotional coping and disease management. In order to measure program impact on concerns most relevant to new RA patients, we developed an evaluation tool incorporating patient identified outcomes (Hewlett, 2003), on which we previously reported. Since that time, we have piloted the evaluation and now report the results.

Methods: Through a multi-level collection of data, we identified patient derived program outcomes and language most relevant to participants. This process yielded 3 key domains: M anaging RA, Connecting with Others with RA and Coping with the Emotional Impact (Wolrich, 2011). From this data we created a 20-item evaluation, using a 6 point Likert scale and open-ended questions, which incorporates patient identified outcomes under each of the domains. This new tool was administered to participants after each of 12 monthly sessions.

Results: 127 evaluations were completed from 180 participants. Demographics: Gender: 93%; M age: 49; Ethnicity: White 59%; African American 19%; Asian American 11%; Latino 11%; Education: College or higher: 92%. Results indicate % of participant agreement (either “completely” or “a great deal”) with the following Likert scale question statements, which represent each of the 3 key domains. I. MANAGING RA: As a result of this program’s value within the 3 domains: M anaging RA, Connecting with Others with RA and Coping with the Emotional Impact (Wolrich, 2011). From this data we created a 20-item evaluation, using a 6 point Likert scale and open-ended questions, which incorporates patient identified outcomes under each of the domains. This new tool was administered to participants after each of 12 monthly sessions.

Results: A total of 132 patients were entered into the study of which 70 received ENAT (53%) and 62 usual care (47%). At week 16, there were no significant between-group differences. By week 32, the ASES mean scores, were higher for the ENAT group than the usual care group; ASES-Pain, MD = 4.36 (95%CI: 1.17, 7.55), t = 2.72, p = 0.008; ASES-Other symptoms, MD = 5.84 (95%CI: 2.07, 9.62), t = 3.07, p = 0.003. (Bonferroni-adjusted P-value = 0.025 for significance at the alpha level). Trends over time revealed significant decrease in the overall ENAT score for all domains (managing pain, movement, arthritis process, self-help measures and support) except the feelings domain. The decrease in the total ENAT score by the end of the study, indicates that patients' educational needs were being met effectively.

Conclusion: This is the first study to report the effects of ENAT-focused education in people with RA. The results of the primary outcome (ASES-Pain and ASES-Other symptoms) suggest that the ENAT could be a useful addition to usual care.

about what I learned); Connecting ("I don’t feel so alone"); Emotional Coping ("learned ways to deal with stress of RA").

**Conclusion:** Evaluation results indicate that in domains I and II, and in domain III, "more confident in managing my RA", the program is making a strong positive impact. In domain III, "RA is less disruptive to my daily life", results reflect positive impact, though not as marked as in other questions. Future work is needed to explore how patients define "disruptive" and develop targeted content to address this for future groups. Future research might also follow participants longitudinally, to determine how program participation over time, and other variables, impact this outcome. This tool was administered to measure how effectively the program meets patient-identified needs. Our process can serve as a model for including the patient perspective in evaluating outcomes in other disease-specific support and education programs.

**Program Evaluation of ‘the Joint Clinic’: An Innovative Clinical Service for Patients with Hip or Knee Osteoarthritis.** J. Haxby Abbert,1 Helen Harcombe,2 Chris Crane,3 Liam Hutton,4 Kirsten Stout,5 Cathy Chapple6 and David Gwynne-Jones.1

1University of Otago, Dunedin, New Zealand, 2Southern District Health Board, Dunedin, New Zealand.

**Background/Purpose:** In socialized healthcare systems with free public access to healthcare, there are circumstances wherein patients referred by general medical practitioners (GPs) for specialist consultation may not be offered a first specialist appointment (FSA), when demand exceeds supply. Thus, clinical prioritization is necessary. To address unmet need for FSA in patients with hip or knee osteoarthritis, we initiated and evaluated a physical therapist-led clinic offering non-surgical management of osteoarthritis and outpatient treatment.

**Methods:** We conducted a program evaluation comprising: a proof-of-concept evaluation, an implementation evaluation, a process evaluation, and an outcomes evaluation. Mixed-methods qualitative and quantitative methodology grounded in health services research were used. Patients, GPs, surgeons, and hospital clinical, management and administrative staff were interviewed and/or surveyed. Patient trajectories were analysed and patient-reported outcome measures were assessed.

**Results:** The concept model was supported by best-practice literature, and was implemented in close concordance with the model proposed. Qualitative interviews and survey data indicate the "Joint Clinic" has been well accepted by key stakeholders and end-users, is functioning well within the host organisation, is accessible and operating at close to intended capacity. In the 2-year evaluation period, the clinic served 358 new patients (53% female, mean(sd) age 66(10), BMI 29.9(7.51) in 637 consultations. Unmet need was reduced by 80% compared with pre-implementation for hip/knee OA patients; 30% overall. 31% of patients experienced clinically significant (~20%) improvement on patient-reported outcome measures. 25% of patients were referred for FSA (mean wait 77 days) for fast-track access to joint replacement surgery. 70% of patients were satisfied to be seen by the "Joint Clinic" instead of an orthopaedic surgeon; 98% were satisfied with the knowledge and expertise of the "Joint Clinic" staff; 80% would recommend the clinic to others. Cost-per-patient was NZ$384 (year 2). The host organisation has accepted the service as value-for-money and sustainable.

**Conclusion:** These data indicate successful implementation and functioning of an innovative service. The service is achieving satisfactory outcomes benefiting patients through clinically significant improvement, monitoring on optimal non-surgical management, or fast-tracked referral for joint replacement surgery.

**Disclosure:** J. H. Abbott, None; H. Harcombe, None; C. Crane, None; L. Hutton, None; K. Stout, None; C. Chapple, None; D. Gwynne-Jones, None.

**Testing of a Newly Developed Computerized Animated Activity Questionnaire for Assessing Activity Limitations in Patients with Hip and Knee Osteoarthritis.** Wilfred FH Peter1, Mick Loos2, Henrica de Vet1, Maxine Enthoven3, Jaap Harlaar1, Leo D. Roorda1, Rudolf Poolman1, Vanessa Scholtes2, Jan Bogard3, Hilda Buitelaar3, Martin P. M. Steultjens4, Ewa M. Roos5, Anne-Christine Ra6, Francis Guillemin7, Maria Graia Benedetti6, Antonio Escobar Martinez9, Nina Østerås10 and Caroline Terwee1

1VU University Medical Center, Amsterdam, Netherlands, 2Amsterdam Rehabilitation Research Center Reade, Amsterdam, the Netherlands, 3Amsterdam, Amsterdam, 4University of Southern Denmark, Odense, Denmark, 5University of Lorraine, Nancy, France, 6INSERM, Centre d’Investigation Clinique - Epidemiologie Clinique (CIC-EC) CIE6, Nancy, France, 7Istituto Ortopedico Rizzoli, Bologna, Italy, 8Baso University Hospital, Bilbao, Spain, 9Diaconhjemmet Hospital, Oslo, Norway.

**Background/Purpose:** Self-report questionnaires and performance-based tests correlate moderately in measuring activity limitations, indicating that they measure different aspects. Self-reports measure mainly how patients think they perform an activity, and is influenced by pain, fatigue or situations they are referring to. This may lead to cross-cultural differences. Performance-based tests measure an artificial situation, is resource-intensive and burdensome for patients. To overcome these drawbacks we developed and tested a pilot version of an Animated Activity Questionnaire (AAQ), which demonstrated some promising features[1]. The aim of this study was to develop a computerized Animated Activity Questionnaire (AAQ) to assess activity limitations in patients with hip/knee osteoarthritis and preliminary testing of its validity and reliability.

**Methods:** Based on the pilot version, International Classifications of Functioning core set for osteoarthritis, focus groups of patients, and existing measurement instruments, the AAQ was developed. In 482 patients correlations were calculated between the Animated Activity Questionnaire (AAQ) and self-reported Hip disability and Knee Injury Osteoarthritis Outcome physical functioning score. In addition internal consistency was calculated. In 65/482 patients also correlations with performance based tests (Stair Climbing Test, Timed Up and Go test, and the 30 second Chair Stand Test) were calculated. Test-retest reliability was assessed by repeated scoring in 56/482 patients.

**Results:** The Animated Activity Questionnaire (AAQ) includes animated videos of 17 basic daily activities with four levels of increasing difficulty (check the following link for two examples: http://kmin-vumc.nl/_14_0.html). Patients were asked to select the video that best matched their own performance. Cronbach’s alpha was 0.95, Correlation with self-reported physical functioning scores was high (0.72). The AAQ correlated moderately with the performance based tests (0.49, 0.44, and 0.57, respectively). Correlations of the AAQ score with pain was lower (0.51) than the correlation of the self-reported physical functioning score with pain (0.75). For test-retest reliability, a Intraclass Correlation Coefficient of 0.97 (95% Confidence Interval 0.93–0.98) was found.

**Conclusion:** A computerized Animated Activity Questionnaire (AAQ) was developed showing a high internal consistency and excellent test-retest reliability. Content validity was considered good, and construct validity is supported by high correlations with self-reported physical functioning and moderate correlations with performance-based tests. The AAQ seems to be less influenced by pain compared with self-reported physical functioning. Since the AAQ needs no reading ability or translation, it has potential for international use. Continuing research will focus on construct validity and cross-cultural validity.
